DE3.1.2.2.6

Specification of AXMEDIS Content Processing Area

Version: 1.5
Date: 10.05.2006
Responsible: Ivan Bruno (DSI) (verified and approved by coordinator)

Project Number: IST-2-511299
Project Title: AXMEDIS
Deliverable Type: report
Visible to User Groups: yes
Visible to Affiliated: yes
Visible to the Public: yes

Deliverable Number: DE3.1.2.2.6
Contractual Date of Delivery: M18
Actual Date of Delivery: 10/05/2006
Title of Deliverable: DE3.1.2.2.6
Specification of AXMEDIS Content Processing Area
Work-Package contributing to the Deliverable: WP3.1
Task contributing to the Deliverable: WP3, WP2
Nature of the Deliverable: report
Author(s): DSI

Abstract: this part includes the specification of components, formats, databases and protocol related to the AXMEDIS Framework area AXMEDIS Content Processing Area, the formatting Engine as module and component for AXCP and the specification of the Javascript classes for the AXMEDIS Script language.

Keyword List: Content production, Javascript, Adaptation tools, formatting, composition, transcoding
**AXMEDIS Copyright Notice**

The following terms (including future possible amendments) set out the rights and obligations licensee will be requested to accept on entering into possession of any official AXMEDIS document either by downloading it from the web site or by any other means.

Any relevant AXMEDIS document includes this license. PLEASE READ THE FOLLOWING TERMS CAREFULLY AS THEY HAVE TO BE ACCEPTED PRIOR TO READING/USE OF THE DOCUMENT.

1. **DEFINITIONS**
   - "Acceptance Date" is the date on which these terms and conditions for entering into possession of the document have been accepted.
   - "Copyright" stands for any content, document or portion of it that is covered by the copyright disclaimer in a Document.
   - "Licensor" is AXMEDIS Consortium as a de-facto consortium of the EC project and any of its derivations in terms of companies and/or associations, see www.axmedis.org
   - "Document" means the information contained in any electronic file, which has been published by the Licensor’s as AXMEDIS official document and listed in the web site mentioned above or available by any other means.
   - "Works" means any works created by the licensee, which reproduce a Document or any of its part.

2. **LICENCE**
   - The Licensor grants a non-exclusive royalty free licence to reproduce and use the Documents subject to present terms and conditions (the Licence) for the parts that are own and proprietary property the of AXMEDIS consortium or its members.
   - In consideration of the Licensor granting the Licence, licensee agrees to adhere to the following terms and conditions.

3. **TERM AND TERMINATION**
   - Granted Licence shall commence on Acceptance Date.
   - Granted Licence will terminate automatically if licensee fails to comply with any of the terms and conditions of this Licence.
   - Termination of this Licence does not affect either party’s accrued rights and obligations as at the date of termination.
   - Upon termination of this Licence for whatever reason, licensee shall cease to make any use of the accessed Copyright.
   - All provisions of this Licence, which are necessary for the interpretation or enforcement of a party’s rights or obligations, shall survive termination of this Licence and shall continue in full force and effect.
   - Notwithstanding License termination, confidentiality clauses related to any content, document or part of it as stated in the document itself will remain in force for a period of 5 years after license issue date or the period stated in the document whichever is the longer.

4. **USE**
   - Licensee shall not breach or denigrate the integrity of the Copyright Notice and in particular shall not:
     - remove this Copyright Notice on a Document or any of its reproduction in any form in which those may be achieved;
     - change or remove the title of a Document;
     - use all or any part of a Document as part of a specification or standard not emanating from the Licensor without the prior written consent of the Licensor; or
     - do or permit others to do any act or omission in relation to a Document which is contrary to the rights and obligations as stated in the present license and agreed with the Licensor

5. **COPYRIGHT NOTICES**
   - All Works shall bear a clear notice asserting the Licensor’s Copyright. The notice shall use the wording employed by the Licensor in its own copyright notice unless the Licensor otherwise instructs licensees.
6. WARRANTY

1. The Licensor warrants the licensee that the present licence is issued on the basis of full Copyright ownership or re-licensing agreements granting the Licensor full licensing and enforcement power.

2. For the avoidance of doubt the licensee should be aware that although the Copyright in the documents is given under warranty this warranty does not extend to the content of any document which may contain references or specifications or technologies that are covered by patents (also of third parties) or that refer to other standards. AXMEDIS is not responsible and does not guarantee that the information contained in the document is fully proprietary of AXMEDIS consortium and/or partners.

3. Licensee hereby undertakes to the Licensor that he will, without prejudice to any other right of action which the Licensor may have, at all times keep the Licensor fully and effectively indemnified against all and any liability (which liability shall include, without limitation, all losses, costs, claims, expenses, demands, actions, damages, legal and other professional fees and expenses on a full indemnity basis) which the Licensor may suffer or incur as a result of, or by reason of, any breach or non-fulfillment of any of his obligations in respect of this License.

7. INFRINGEMENT

1. Licensee undertakes to notify promptly the Licensor of any threatened or actual infringement of the Copyright which comes to licensee notice and shall, at the Licensor’s request and expense, do all such things as are reasonably necessary to defend and enforce the Licensor’s rights in the Copyright.

8. GOVERNING LAW AND JURISDICTION

1. This Licence shall be subject to, and construed and interpreted in accordance with Italian law.

2. The parties irrevocably submit to the exclusive jurisdiction of the Italian Courts.

Please note that:

- You can become affiliated with AXMEDIS. This will give you the access to a huge amount of knowledge, information and source code related to the AXMEDIS Framework. If you are interested please contact P. Nesi at nesi@dsi.unifi.it. Once affiliated with AXMEDIS you will have the possibility of using the AXMEDIS specification and technology for your business.
- You can contribute to the improvement of AXMEDIS documents and specification by sending the contribution to P. Nesi at nesi@dsi.unifi.it
- You can attend AXMEDIS meetings that are open to public, for additional information see WWW.axmedis.org or contact P. Nesi at nesi@dsi.unifi.it

1.1 This document concerns

This document is focused on producing an update of the specification to be adopted as a baseline in the specification tasks of the different work packages that will be developed in XXXX months of the project. The part C of the specification deals with problems related to the Content Production and more in general with content processing, therefore the specification of the Content Processing and tools are reported. Specification Part C is structured in 3 main sections dealing with different aspects of content production:

- **AXMEDIS Content Processing Area** (under responsibility of DSI). This section describes the goals, the activity and tools of AXMEDIS Content Processing Area. This area copes with the problem of automatic content production, adaptation and protection of AXMEDIS object and their publication on a P2P environment (AXEPTool). The proposed solution is based on rules that include a procedural description using the Javascript language (script) and a Javascript engine for the their execution. The JavaScript engine is derived from SpiderMonkey by Mozilla. To cope with the amount of needed resources (computational, time, etc…) during the content processing activity, a distributed environment has been defined and based on GRID computing. The AXMEDIS Content Processing Area specification is then further illustrated by means of UML diagrams, scenarios, tables, GUI definitions and design, definition of a Grid communication protocol and the XML schema for rules.

- **AXMEDIS Content Format Engine** (under responsibility of DSI). This section describes the goals, of the AXMEDIS Content Format Engine. This area copes with the formatting functionalities that are used by the AXCP GRID and by format tools (Template Editor and Selector, Style Editor and Selector, Style Optimizer) integrated within the AXMEDIS SMIL Editor. The goal of the Content Format Engine is integrating digital resources, contained within an AXMEDIS Object, in a multimedia presentation (based on the SMIL language) suitable for the final user.

- **AXMEDIS Data Types and functions for JavaScript Engine.** In this section how to use C++ classes and functions in the Spidermonkey Javascript engine are described. This mechanism has been used to wrap the set of classes (methods and attributes) and functions to be used with the Javascript code The current set of classes and functions are also reported.

1.2 List of Modules or Executable Tools Specified in this document

<table>
<thead>
<tr>
<th>Module/tool Name</th>
<th>Module/Tool Description and purpose, state also in which other AXMEDIS area is used</th>
<th>Standards exploited if any</th>
</tr>
</thead>
<tbody>
<tr>
<td>AXCP Rule Model</td>
<td>It models the AXCP rule and provides loader/saver functionality to load and save rules</td>
<td>AXMEDIS common and XERCES v2-6 libraries</td>
</tr>
</tbody>
</table>
| AXCP Rule Editor         | The application is an executable GUI for creating, editing, saving, testing and activating AXCP rules Other AXMEDIS Modules include:  
  - AXCP Rule Model  
  - AXCP Rule Executor for testing rules  
  - AXMEDIS Configuration Manager for application  
  - AXMEDIS Plugin Manager for Rule Editor Workflow plugin and AXCP Plugins  
  - AXMEDIS Content Processing Plugins  
  - AXMEDIS Selection Editor | It exploits the AXCP Rule Model AXMEDIS Framework, AXCP Rule Executor and XERCES v2-6 libraries |
| AXCP Rule Engine         | It consists in:  
  - AXCP Rule Scheduler: the application in charge to manage AXCP rules and schedule their execution in the GRID environment  
  - AXCP Rule Executor: it is an instance of the Rule executor in the GRID environment and executes AXCP rules  
  - AXMEDIS Configuration Manager for application  
  - AXMEDIS Plugin Manager for Rule Scheduler Workflow and AXCP Plugins  
  - AXMEDIS Content Processing Plugins | It exploits the AXCP Rule Model AXMEDIS Framework, AXCP Rule Executor and XERCES v2-6 libraries |
1.3 List of Formats Specified in this document

<table>
<thead>
<tr>

</table>

1.4 List of Databases Specified in this document

<table>
<thead>
<tr>
<th>Database Name</th>
<th>database Description and purpose, state also in which other AXMEDIS area is using</th>
<th>Standards exploited if any</th>
</tr>
</thead>
<tbody>
<tr>
<td>AXMEDIS Database</td>
<td>Accessed using the AXOM loader and saver tools</td>
<td></td>
</tr>
<tr>
<td>Protocol Name</td>
<td>protocol Description and purpose, state also in which other modules is used</td>
<td>Who is the master and who is the slave</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>----------------------------------------</td>
</tr>
</tbody>
</table>
| AXCPGridRuleEngine    | It is a ASCII based set of commands used as communication support in the GRID environment. It is used in:  
|                       | AXCP Rule Scheduler  
|                       | AXCP Rule Executor | AXCP Rule Scheduler is the master and AXCP Rule Executors are slaves |
2 General Use Cases and scenarios

The use case for the AXMEDIS Content Processing Area includes:
- Use case 2.1: Editing and Activation of an AXCP rule
- Use case 2.2: Execution of a rule in the AXCP Rule Engine

2.1 Use Case: Editing and Activation of an AXCP rule
The use case shows how AXCP rules are produced.

Scenario description for the activation and modification of an existing rule:
1. The actor loads an existing AXCP rule from the rules database or starts with a new rule
2. The actor edits the rule by the AXCP Rule Editor
3. The actor saves the new rule into the rules database
4. The actor activate the rule
5. The rule is sent to rules repository of the AXCP Rule Engine.

2.2 Use Case: Execution of a rule in the AXCP Rule Engine
The use case shows the execution of a rule in the AXCP Rule Engine.
Scenario description:

1. **Start process.** The AXCP Rule Engine receives a running rule request coming from the AXMEDIS Workflow Manager, or from the AXMEDIS Publication & Programme, or from the internal scheduler that activates an AXCP rule.

2. **Rule execution request.** The scheduler sends the rule execution request to the rule executor with the corresponding rule (*Running rule*).

3. **AXMEDIS Objects selection request.** For each selection and/or query specified in the rule, the rule executor sends queries to the AXMEDIS Query Support to obtain references to AXMEDIS objects that match the request.

4. **AXOM usage.** An embedding object request with the relative object reference is sent to the AXOM to perform the inclusion.

5. **Physical Objects request.** The physical object is requested to the AXMEDIS Database by means of its reference.

6. **Adaptation request.** This request is performed via AXOM in order to perform a formatting paradigm or a set of customised formatting parameters. This phase could:
   a. Perform adaptation algorithm (change resolution, change dimension, time or spatial best fitting, etc…)
   b. Apply spatial and temporal constraints specified in the rule (i.e. graphical layout, temporisation, transitions effects, etc…)
   c. Perform synchronisation algorithm (audio and text audio and images, video and text, etc…)
   d. Convert the whole formatted object into a specific output format (i.e. MPEG4).

7. **External tools calling.** This request allows calling external functionalities available on external formatting tools. In this way some formatting operation can be delegated and performed in other formatting environment. These calls are properly coded in the formatting rule and refer to portion of code written by using for example the script language available on the external tool.
8. **Fingerprint request.** This request is performed via AXOM in order to apply the fingerprint to the formatted object according to the fingerprint parameters specified in the rule.

9. **Protection request.** This request is performed via AXOM. A protection request is sent to the Protection tool in order to apply protection to the new AXMEDIS formatted object.

10. **Storing AXMEDIS object.** The new formatted AXMEDIS Object is stored into the AXMEDIS Database.

11. **End process notification.** The End of the formatting process is notified to the AXMEDIS Workflow Manager.

### 2.3 Use Case:

The use case shows usage of high-level functionalities offered by Content Formatting Engine

Automatic formatting:
1. Automatic template selection
2. Automatic style-sheet selection
3. Automatic style-sheet optimization
4. Format creation

Interactive formatting:
1. Interactive template selection
   1.1. A new template may be created
2. Interactive style-sheet selection
   2.1. A new style-sheet may be created
3. Interactive style-sheet optimization
4. Format creation
3 AXMEDIS Content Processing Area General architecture and relationships among the modules produced

In this section, main actors involved in the AXMEDIS Content Processing Area are described. The picture, reported below, shows the unified solution and relationships among the AXMEDIS Workflow Manager, the AXCP Rule Editor and Engine plus the AXMEDIS Content Processing tools.

1. **Workflow Manager** – It performs the role of supervisor by monitoring and controlling the AXCP Rule engine and editor activity.
2. **AXCP Rules Editor** – It is an editor for writing protection, production and publication on AXEPTool rules. It is supported by a repository of rule rules and interacts with the AXCP Rule Engine.
3. **AXCP Rule Engine** – It performs the automatic production, protection, adaptation, gathering, P2P publication processes by means specific AXCP rules. It generates new composite, formatted, adapted, protected AXMEDIS objects, gathers raw contents, etc…. Such objects are successively stored in the AXMEDIS database or delivered via distribution channels or published by means the AXEPTool. The Engine is supported by following modules and tools:
   a. **Protection** – It provides functionalities and algorithms performing the protection of the AXMEDIS object via Protection Support
   b. **Fingerprint** – It provides functionalities and algorithms performing the Fingerprint estimation of a new AXMEDIS object. The fingerprint could be based on component’s fingerprint or could be a new one.
   c. **Adaptation** – It provides functionalities and algorithms performing the Content adaptation for different distribution channels and format paradigm.
   d. **External tools** - Tools for using external formatting functionalities. It provides a set of plug-ins that allow using external tools (Macromedia suite, Adobe suite, etc…) and extending functionalities of the composition and formatting engine and AXMEDIS Editor.
   e. **Publication on AXEPTool** – It provides functionalities and algorithms performing metadata manipulation and mapping, publication of AXMEDIS object on the AXEPTool.
3.1 AXCP Content Processing area UML Decomposition

In this section the UML decomposition of the AXMEDIS Content Processing Area is described. It represents the unified solution based on the AXMEDIS Content Processing Rule Engine (AXCP Rule Engine) and that integrates the following engines:

- AXMEDIS Composition and Formatting Engine
- AXEPTool Loading Tool Engine
- AXEPTool Publication Tool Engine
- AXEPTool P2P Active Selection Engine
- The Protection Tool Engine

According to the UML diagram, the AXMEDIS Content Processing Area includes:

- **AXCP Rule Editor**: A graphic editor that allows writing and editing composition, formatting, adaptation, crawling, protection and publication on AXEPTool rules.
- **Repository of AXCP Rules**: It is a simple repository of rules; it is the file systems or a database. The rules are described by means an XML schema.
- **Active Rules**: They are rules that are scheduled to be run by the AXCP Rule Engine.
- **AXCP Rule Engine**: It consists in a scheduler of rules and a set of rule executors placed in a GRID environment.
- **AXMEDIS Database Manager**: It allows the engine to retrieve AXMEDIS objects involved in the execution of a rule.
- **AXMEDIS Query Support**: It allows the engine to submit queries to the AXMEDIS Database Manager.
- **AXMEDIS Object Manager (AXOM)**: It allows managing AXMEDIS objects during the execution of a rule. It provides functions and methods for manipulating and managing resources and metadata.
- **AXOM Content Processing**: It is based on a Plugin Manager and the External Procedures Profile Manager. It allows extending the engine capabilities by providing the interface to Plug-ins such as:
  - **Adaptation Tools and Algorithms as Plugin for AXOM**: They are a collection of algorithms and tools that provides functions for content adaptation. The role of such component is to provided different methods to manipulate digital contents in order to satisfy several and different user profile.
  - **Fingerprint/Descriptor Estimation Tools as Plugin for AXOM**: They are a collection of algorithms and tools that provide functions for fingerprint/descriptors estimation from digital contents.
- **Protection Manager support**: It provides the support to manage the protection of AXMEDIS objects.
- **AXEPTool Publication Module**: It provides the support to manage the publication aspects in the AXEPTool.
- **AXEPTool Loading Module**: It provides the support to manage the publication aspects in the AXEPTool.
- **AXEPTool P2P Active Selection Module**: It provides the support to manage the publication aspects in the AXEPTool.

### 4.1 General Description of the Module

The entire production process is driven by rules called AXMEDIS Content Processing rules (AXCP Rule). They allow an automatic and customizable process that responds to the distribution and end user needs.

A rule have to:

- describe what resources are involved in the processing (i.e. extracting digital resources from the AXMEDIS database by means of queries built on metadata and licensing information or from a composite AXMEDIS object);
- describe distribution channel properties, user device features, user profile, etc…
- describe the final output using a specific integration format (MPEG-4, SMIL,…) or using DIP capabilities provided by MPEG-21 objects
- describe how to combine different digital resources and create relationships in terms of:
  - spatial relationships (for graphic layout, resource adaptation, …)
  - time relationships (for synchronisation, transitions effect, fitting (shrinking or stretching, cutting, …));
- describe how to manage and combine DRM rules for the new formatted resource;
- describe operations or actions that have to be performed during the formatting process, for example:
  - which formatting algorithms have to be used (synchronisation, image scaling, resolution scaling, format conversion, etc…)
  - which external functionalities (by dynamic call to services provided by external tools) have to be used
    - Fingerprint estimation and application for the new composite item
    - Object ID assignment for the new composite item.
- describe how to protect resources
In general, a rule could be formalised as a function in the following way:

\[ R = f(S_1, S_2, ..., S_n, P_1, ..., P_m) \]

Where:
- \( S_i \) – It defines a selection. It is a sequence of query to be sent to the Query Support for AXMEDIS objects retrieval or references to digital resource embedded into an composite AXEMDIS object;
- \( P_i \) – It is a parameter (basic type as integer, string, Boolean);
- \( f \) is the identifier of rule (name of rule or other);
- \( R \) is the resultant of rule application. It will be a new AXMEDIS object, or a metadata manipulation, the protection of an AXMEDIS object, etc…

In this section the structure of a rule is described. A rule is constituted of three main sections:
- **Header** – General metadata about the AXCP rule
- **Schedule** – Temporal metadata that describes conditions for firing the AXCP rule
- **Definition** – The definition of the AXCP rule

**Header**

This section contains metadata related to general information associated with a rule. It is constituted of:

<table>
<thead>
<tr>
<th>Data</th>
<th>Type</th>
<th>Values/Format</th>
<th>Description</th>
<th>Issues</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rule Name</td>
<td>String</td>
<td>e.g. “Audio Collection”</td>
<td>It defines the name of the rule</td>
<td></td>
</tr>
<tr>
<td>AXRID</td>
<td>String</td>
<td></td>
<td>It defines the AXMEDIS Rule ID</td>
<td></td>
</tr>
<tr>
<td>Rule Version</td>
<td>String</td>
<td>e.g. “1.0”</td>
<td>It defines the version of the rule</td>
<td></td>
</tr>
<tr>
<td>Rule Type</td>
<td>String</td>
<td>AXCP Rule, AXPnP Rule</td>
<td>It defines the type of rule</td>
<td>AXCP rules identifies all rules related to the Content Processing Area, whereas the AXPnP rules are the rule of the P&amp;P area</td>
</tr>
<tr>
<td>Software Name</td>
<td>String</td>
<td>“Axmedis Rule Editor”</td>
<td>It specifies the name of software used</td>
<td></td>
</tr>
<tr>
<td>Version of software</td>
<td>String</td>
<td>e.g. “2.0”</td>
<td>It defines the version of software used.</td>
<td></td>
</tr>
<tr>
<td>Date of production</td>
<td>Date</td>
<td>dd.mm.yy</td>
<td>It defines when the rule has been created</td>
<td></td>
</tr>
<tr>
<td>Time of production</td>
<td>Time</td>
<td>hh.mm.ss am/pm</td>
<td>It defines at what time the rule has been created</td>
<td></td>
</tr>
<tr>
<td>Author</td>
<td>String</td>
<td>e.g. “John Brown”</td>
<td>It defines the name of author who has created the rule</td>
<td></td>
</tr>
<tr>
<td>Affiliation</td>
<td>String</td>
<td>e.g. “DSI”</td>
<td>It defines the name of Affiliation</td>
<td></td>
</tr>
<tr>
<td>URL</td>
<td>String</td>
<td>e.g. “<a href="http://www....%E2%80%9D">http://www....”</a></td>
<td>It defines the Internet address of the Affiliation</td>
<td></td>
</tr>
<tr>
<td>Comment</td>
<td>String</td>
<td></td>
<td>It allows describing what the rule does</td>
<td></td>
</tr>
<tr>
<td>Last_Modification</td>
<td>Date</td>
<td></td>
<td>Who is last modified</td>
<td></td>
</tr>
<tr>
<td>Terminal_ID</td>
<td>String</td>
<td></td>
<td>The Id of the terminal used to write the rule.</td>
<td></td>
</tr>
<tr>
<td>Cost</td>
<td>Enum</td>
<td></td>
<td>Estimation of Cost</td>
<td></td>
</tr>
</tbody>
</table>
Schedule
This section contains the sequence of metadata for programming the activation of a rule:

<table>
<thead>
<tr>
<th>Schedule</th>
<th>Data</th>
<th>Type</th>
<th>Values/Format</th>
<th>Description</th>
<th>Issues</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Run</td>
<td>Section</td>
<td></td>
<td>It defines a subsection of metadata that describe information needed for scheduling the execution of the rule.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Status</td>
<td>String</td>
<td>“Active”, “Inactive”</td>
<td>It defines if a rule: • is active and can be executed • is inactive</td>
<td>The list of status identifiers could be extended if it is necessary.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Run</th>
<th>Data</th>
<th>Type</th>
<th>Values/Format</th>
<th>Description</th>
<th>Issues</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Start Date</td>
<td>Date</td>
<td>dd.mm.yy</td>
<td>It defines when the rule has to be executed by the engine in terms of day, month and year.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Start Time</td>
<td>Time</td>
<td>hh.mm.ss am/pm</td>
<td>It defines when the rule has to be executed by the engine in term of time clock.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Periodicity</td>
<td>String</td>
<td>“Monthly”, “Daily”, “Weekly”, etc…</td>
<td>It defines if a rule has to be executed periodically</td>
<td>Optional</td>
</tr>
<tr>
<td></td>
<td>Expiration date</td>
<td>Date</td>
<td>dd.mm.yy</td>
<td>To stop the periodicity</td>
<td>Optional</td>
</tr>
<tr>
<td></td>
<td>Expiration time</td>
<td>Time</td>
<td>hh.mm.ss am/pm</td>
<td>To stop the periodicity</td>
<td>Optional</td>
</tr>
</tbody>
</table>

Definition
This section include the AXCP Rule section containing the procedural description of the rule.

<table>
<thead>
<tr>
<th>AXCP Rule</th>
<th>Data</th>
<th>Type</th>
<th>Values/Format</th>
<th>Description</th>
<th>Issues</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>Section</td>
<td></td>
<td></td>
<td>It includes the set of selections and parameters that rule has in input.</td>
<td></td>
</tr>
<tr>
<td>Preconditions</td>
<td>Section</td>
<td></td>
<td></td>
<td>It includes the list of DLL/functions, Plug In used by the script preconditions</td>
<td>This is information could be used to check the feasibility of rule before running it</td>
</tr>
<tr>
<td>Rule Body</td>
<td>Section</td>
<td></td>
<td></td>
<td>It includes the JavaScript code that defines the Rule</td>
<td></td>
</tr>
<tr>
<td>Files Complexity</td>
<td>TBD</td>
<td>TBD</td>
<td></td>
<td>It will specify the complexity of the rule in terms of computational, file transfer parameters, estimated amount of disk space required by the digital resources involved in the rule and other parameters</td>
<td>This will be better defined during the project life</td>
</tr>
</tbody>
</table>

The Arguments subsection contains the list of Selections and Parameters that will be used by the rule.

For each Selection see the “XML Selection Schema” in Part E.
Each *Parameter* is defined as following:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Data</th>
<th>Type</th>
<th>Values/Format</th>
<th>Description</th>
<th>Issues</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>String</td>
<td></td>
<td></td>
<td>It specifies the name of the parameter</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
<td></td>
<td>Integer, String, Float, Double, etc…</td>
<td>It specifies the type of parameter</td>
<td></td>
</tr>
<tr>
<td>Value</td>
<td>string</td>
<td></td>
<td></td>
<td>It specifies the value that the parameter assumes</td>
<td></td>
</tr>
</tbody>
</table>

The Preconditions subsection contains information about the AXMEDIS Editor Plug In that could be required by the Rule Body. This mechanism is similar to the *import* directive in JAVA language.

<table>
<thead>
<tr>
<th>Preconditions</th>
<th>Data</th>
<th>Type</th>
<th>Values/Format</th>
<th>Description</th>
<th>Issues</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plug_In_Name</td>
<td>String</td>
<td></td>
<td>e.g.: “Adaptation”</td>
<td>It provides the name of the AXMEDIS Editor Plug In used by the script. This information has to be matched with that provided by the DLL from its profile.</td>
<td></td>
</tr>
<tr>
<td>Version</td>
<td>String</td>
<td></td>
<td>e.g.: “2.0”</td>
<td>Version of the Plug In. This information has to be matched with that provided by the DLL from its profile.</td>
<td></td>
</tr>
</tbody>
</table>

The Rule Body section provides two possible ways to refer the adopted script:

<table>
<thead>
<tr>
<th>Rule Body</th>
<th>Data</th>
<th>Type</th>
<th>Values/Format</th>
<th>Description</th>
<th>Issues</th>
</tr>
</thead>
<tbody>
<tr>
<td>JS_Script</td>
<td>String</td>
<td></td>
<td>e.g. “Script Name”</td>
<td>It could be used to embed the whole script (JavaScript code) inside the XML rule format.</td>
<td>Choice</td>
</tr>
<tr>
<td>Path</td>
<td>URL</td>
<td></td>
<td></td>
<td>It could be used to specifies reference to a “.js” file that contains the source script of the current rule (JavaScript code).</td>
<td>Optional</td>
</tr>
</tbody>
</table>

### 4.2 AXCP Rule XML Schema

The following XML schema refers to the “Rule_Axmedis.xsd” file.

```xml
<xs:element name="Rule">
  <xs:complexType>
    <xs:sequence>
      <xs:element name="Rule_Name" type="xs:string"/>
    </xs:sequence>
  </xs:complexType>
</xs:element>
```
<xs:element name="AXRID" type="xs:string/>
<xs:element name="Rule_Version" type="xs:string"/>
<xs:element name="Rule_Type">
    <xs:simpleType>
        <xs:restriction base="xs:string">
            <xs:enumeration value="AXCP"/>
            <xs:enumeration value="AXPnP"/>
        </xs:restriction>
    </xs:simpleType>
</xs:element>
<xs:element name="Software_Name" type="xs:string"/>
<xs:element name="Version_of_software" type="xs:string"/>
<xs:element name="Date_of_production" type="xs:date"/>
<xs:element name="Author" type="xs:string"/>
<xs:element name="Affiliation" type="xs:string"/>
<xs:element name="URL" type="xs:anyURI"/>
<xs:element name="Comment" type="xs:string"/>
<xs:element name="Last_Modifications" type="xs:date"/>
<xs:element name="Terminal_ID" type="xs:string"/>
<xs:element name="Cost" type="xs:string"/>
<xs:element name="Work_Item_ID" type="xs:string"/>
</xs:sequence>
</xs:complexType>
</xs:element>

<xs:element name="Schedule">
    <xs:complexType>
        <xs:sequence>
            <xs:element name="Run">
                <xs:complexType>
                    <xs:sequence>
                        <xs:element name="Date" type="xs:date"/>
                        <xs:element name="Time" type="xs:time"/>
                        <xs:element name="Periodicity" minOccurs="0">
                            <xs:complexType>
                                <xs:simpleContent>
                                    <xs:extension base="xs:integer">
                                        <xs:attribute name="Unit" type="periodunit"/>
                                    </xs:extension>
                                </xs:simpleContent>
                            </xs:complexType>
                        </xs:element>
                        <xs:element name="Expiration_Date" type="xs:date" minOccurs="0"/>
                        <xs:element name="Expiration_Time" type="xs:time" minOccurs="0"/>
                    </xs:sequence>
                </xs:complexType>
            </xs:element>
            <xs:element name="Status">
                <xs:simpleType>
                    <xs:restriction base="xs:string">
                        <xs:enumeration value="Active"/>
                        <xs:enumeration value="Inactive"/>
                    </xs:restriction>
                </xs:simpleType>
            </xs:element>
        </xs:sequence>
    </xs:complexType>
</xs:element>

<xs:element name="Definition">
    <xs:complexType>
        <xs:choice minOccurs="0" maxOccurs="unbounded">
            <xs:element name="AXCP_Rule">
                <xs:complexType>
                    <xs:sequence>
                        <xs:element name="Arguments">
                            <xs:complexType>
                                <xs:choice maxOccurs="unbounded">

    <xs:enumeration value="Week"/>
    <xs:enumeration value="Year"/>
  </xs:restriction>
</xs:simpleType>

Selection XML schema is defined as following:

The file associated with the rule is an XML file whose name will be generated as following:

```
< Rule_Filename > = <Rule_Name> + <Rule_Version> + AXRID + ".xml "
```

### 4.3 Examples of usage

The following example shows the XML structure for a generic rule:

```
<Rule>
  <Header>
    <Rule_Name> Audio Collection </Rule_Name>
    <AXRID> 0010001 </AXRID>
    <Rule_Version> 1.0 </Rule_Version>
  </Header>
```

*AXMEDIS Project*
4.4 AXCP Rule Model

According to the XML schema, the object oriented model of the rule is described by the class diagram reported in the Figure A and B. Actually, the current status of the model is close to the final version. Implementation was realised in C++ MSVC7 and supported by the XERCES 2.6.0 libraries.

AxDOMImplementation Class

The AxDOMImplementation class specialises the ErrorHandler interface class of the XERCES library ver. 2.6.0. by redefining the pure virtual methods:

- virtual void warning (const SAXParseException &exc)=0
  Receive notification of a warning.  
  [http://xml.apache.org/xerces-c/apidocs/classErrorHandler.html#z819_0](http://xml.apache.org/xerces-c/apidocs/classErrorHandler.html#z819_0)
- virtual void error (const SAXParseException &exc)=0
Receive notification of a recoverable error. [http://xml.apache.org/xerces-c/apiDocs/classErrorHandler.html - z819_1#z819_1]

- virtual void **fatalError** (const **SAXParseException** &exc)=0

Receive notification of a non-recoverable error. [http://xml.apache.org/xerces-c/apiDocs/classErrorHandler.html - z819_2#z819_2]

- virtual void **resetErrors** ()=0

Reset the Error handler object on its reuse.

Such methods are called if the validation of the XML Rule file fails during the parsing. The **AxDOMImplementation** class does not consider warnings and puts the **fSawErrors** attribute at **true** when an error occurs. The **getSawErrors()** method returns the **fSawErrors** value and then allows evaluating the result of validation. The class provides a pointer to the DOM tree (**DOMDoc**) of the all XML rule and is fixed by the **buildDOMDoc()** method. Such method was defined as virtual demanding its implementation to the **AxRule** class. It is equipped with a **XercesDOMParser** (**parser**) for loading the whole rule and **XercesDOMParser** (**parser**) for managing the XML string of a **Selection** in independent manner when saving the rule.

**AxRuleHeader Class**

The rule header is the class for storing the AxRule header information with access methods. It manages all properties of the **Header** section according to the XML schema. It provides getter and setter methods to access attributes.

**AxRuleSchedule Class**

The rule schedule is the class for storing the AxRule schedule information with access methods. It manages all properties of the **Schedule** section according to the XML schema. It provides getter and setter methods to access attributes.
AxRule Class
The AxRule is the main class for a rule. It specialises the AxDOMImplementation and redefines the buildDOMDoc() method for building the DOM tree during the load and save phases. It encapsulates the AxRuleHeader and the AxRuleSchedule class. In this way, the AxRule class is the common class for the AXCP and AXPnP rules. Each of them has to define the Definition section according to Rule XML Schema in order to specialise the AXRule. The AxRule class provides the buildXMLString() to build a string reporting the XML code of the rule, the load(), save() and saveAs() methods. The loading and saving methods instantiate an AxRuleVisitor object that is passed as argument to the visit() method. The AxRuleVisitor object will be an AxRuleLoader when loading and an AxRuleSaver when saving; in both case the polymorphic visit() method is called.

AxCPRule Class
It specialises the AxRule class and inherits all methods. It adds methods and attributes to manage the Definition section of the XML schema. AxRuleSScriptList, AxRuleArgumentList and AxRuleDependencyList contain respectively AxRuleJSScript, AxRuleArgument and AxRuleDependecy object, they model scripts, arguments and dependencies of the rule. The class provides also direct access methods to the internal list (getter and setter, item counting, access and removal).

AxRuleJScriptList
This class manages the list of javascript objects, It provides methods for accessing, reading, adding, removing a AxRuleJScript object.

AxRuleJScript
The AxRuleJSScript models a javascript object. The class provides also the scriptName of script (e.g. filename). The javascript source code is stored in the javaScriptCode string attribute. Optionally, a file with the javascript code could be referred by means the path string attribute. The included Boolean attribute stands for a status of the script: when it is true the script is included by reference using path otherwise is embedded in the XML of rule. The client void pointer stands for a reference to a data structure such as client data in the GUI.

AxRuleArgumentList
This class manages the list of arguments, It provides methods for accessing, reading, adding, removing a AxRuleArgument object.

AxRuleArgument
The AxRuleArgument models a generic argument of rule. The argId attributes specifies if the argument is a parameter (axID_PARAMETER) or a selection (axID_SELECTION). The class provides also the name attribute.

AxRuleParameter
It specialises the AxRuleArgument by defining the type and the value of the parameter. The value attribute is stored as string, whereas the type is associated with the enumerate values (axINTEGER =0, axREAL ,axSTRING, axXMLSTRING, axDATE, axTIME, axBOOLEAN, axURL, axNULL).

AxRuleSelection
It is a particular type of parameter. A selection is stored as a full XML string according to the Selection schema. The AxRuleSelection class specialises the AxRuleParameter by adding a method (updateXML()) to manage the change of the selection name directly on the XML string when calling the setName() method.

AxRuleDependencyList
This class manages the list of dependencies. It provides methods for accessing, reading, adding, removing a AxRuleDependency object.

AxRuleDependency
This class manages the dependency of the javascript code to a specific Axmedis plugin. It provides getter and setter methods to access dependencyName, pluginName and pluginVersion attributes.

4.5 AXRule Loader and Saver Modules (DSI)

To manage the repository of rules it is necessary to load and save a rule in/from the system. The Rule Load and Save functionalities was designed and implemented by means of the following classes:

**AXRule Loader** - It is the module for loading an XML representation of the rule in the AXCP Rule Editor and AXCP Rule Engine. It works according to the XML rule specification and provides the following functionalities:

- Load the XML file of the AXCP rule from disk and generates an AXCP memory representation of rule (AxCPRule object)

**AXRule Saver** – It is the module for saving an XML representation of the rule on disk. It works according to the XML rule specification. It provides the following functionalities:

- Save the XML representation of the rule by replacing the existing one
• Save as function for saving the XML representation of the rule with a name

Both modules was implemented by using an abstract class called AXRuleVisitor as reported in the UML diagram. This solution allows building an AXRuleLoader and an AXRuleSaver class that manage different types of rules by implementing different Visit methods (see the class diagram reported below). Both classes are related to a DOM Document in order to perform the necessary read/write operations on an XML file. The XML representation of a rule is stored in the DOMDocument class from which it is possible to build the memory representation of the AXCP rule. The AXRule class provides a Load and Save method and a virtual method Visit that have to be redefined in the AXCP Rule class. In this way, the Visit method of AXCP Rule calls the Visit method of AXRuleLoader on the AXCP Rule object by using the this pointer.

Implementation was realised in C++ MSVC7 and supported by wxWidgets ver. 2.4.2 and XERCES 2.6.0 libraries.

4.5.1 AxRuleVisitor Class
This class defines an abstract class for a Visitor. This class allows building a Loader and a Saver that manage different types of rules by implementing different Visit methods. The loader and saver visitor were implemented as specialized class of AxRuleVisitor.

4.5.2 AxRuleLoader Class
This class is a specialisation of the AxRuleVisitor class and implements a visitor for loading both AxRule and AxCPRule XML file. Since AxRule contains only Header and Schedule section, the visitor loader for such rule will read only Header and Scheduler sections. The visitor loader for the AxCPRule will call the visitor loader of the AxRule and then will read the Definition section. Methods of this class work polymorphically.

4.5.3 AxRuleSaver Class
This class is a specialisation of the AxRuleVisitor class and implements a visitor for saving both AxRule and AxCPRule XML file. Since AxRule contains only Header and Schedule section, the visitor saver for such rule will write only Header and Scheduler sections. The visitor saver for the AxCPRule will call the visitor saver of the AxRule and then will write the Definition section. Methods of this class work polymorphically.
UML Class Diagram of the AxRuleLoader and AxRuleSaver modules
## 5 AXCP Rule Editor (DSI)

5.1 General Description of the Module

The AXCP Rule Editor is the tool that permits to obtain well formed rules by the means of both graphic and scripting tools. The AXCP Rule Editor is launched by the Workflow Web User Interface when the user/Rule producer clicks on a specified button in the Web page. During the launching an incomplete Rule XML is sent to the AXCP Rule Editor. Some information could be already available in the header of rule (rule type, AXRID, comments etc…) and in the schedule. The Rule Editor is able to interact with an instance of the Rule Executor derived from the AXCP Rule Engine in order to perform debugging and feasibility check on rules. The main capabilities provided by the editor are:

- AXCP rule editing
- AXCP Rule Activation
- Internal textual editor for writing the Javascript code
- Debugging support to test and verify the Javascript code
- Communication support with the AXCP Rule Engine
- Communication support with the AXMEDIS Workflow Manager
- Selection editing and testing
- Metadata mapping
The specific components and aspects regarding protection and DRM can be found in section 5.2 of part H of the AXMEDIS framework specification “Protection Rule Editor”.

5.2 AXCP Rule Editor UML description

Compositional/Formatting Rule Editor
To be taken as an example of others Rule/Selection EDITOR
5.3 AXCP Rule Editor User Interface (DSI)

The AXCP Rule Editor is an IDE and multithread application and has been developed by using the wxWidgets ver. 2.4.2 library. This should allow having a multiplatform rule editor.

The AXCP Rule Editor GUI has been designed as MDI window that manages a rule document a time. It has been developed to provide a set of tools and views to help the user during the editing and production of rule. It hosts an instance of the AXCP Rule Executor in order to provide functionalities for debugging, testing and validating the script code associated with a rule. To help the user in writing rule, the editor has been equipped with an Help on line and an area where the user can access to a library of functions provided by AXMEDIS plugins and Javascript AXMEDIS classes and utilities. The main architecture of GUI is based on the following structure:
5.3.1 The Menu Bar

The menu bar is constituted of the following entries:

- **File**
  - New – Create a new rule document
  - Open – Open an AXCP rule in the Rule Editor
  - Close – Close the current rule document
  - Save – save the current rule using the current file name
  - Save as – save the current rule by name
  - Import JScript – import a script in the rule
  - Export JScript – export the script on file system
  - Properties – it shows a report on the
  - Page setup – allow preparing the page for printing document
  - Print preview – open the print preview dialog
  - Print – send the document to the printer
  - Recent Files – History of files
  - Exit – Quit the editor

- **Edit**
  - Copy – copy a text selection in the clipboard
  - Paste – paste a text selection available in the clipboard
  - Cut – delete and copy a text selection in the clipboard
  - Delete – delete a selected item
  - Find… – Search a word in the text
  - Find next – search again for a new location of the current text
  - Replace… – replace a word with another
DE3.1.2.2.6 – Specification of AXMEDIS Content Production

- **Replace again** – replace again the word with a new entry
- **Match brace** – match the brace
- **Go to…** – go to a specific line text
- **Advanced menu:**
  - Indent increase
  - Indent reduce
  - Overwrite mode
  - Wrap mode
  - Show line endings
  - Show indent guides
  - Show line numbers
  - Show long line markers
  - Show whitespace
- **Select All** – select all content
- **Select line** – select the line where cursor is blinking

**View**
- **Workspace** – It opens the Workspace area
- **Output** – It opens the Output area

**Insert**
- **Selection** – Adds a selection item in the rule
- **Parameter** – Adds a parameter item in the rule
- **Script** – Adds a script item in the rule
- **Dependency** – Adds a dependency item in the rule

**Commands**
- **Activate Rule** – It is the activate rule command and will allow sending the current rule to the scheduler and notification to the AXMEDIS Workflow Manager. A connection with the Rule Engine Scheduler will be open in order to perform the installation of rule in the Scheduler.
- **Check rule** – Tests the feasibility of the rule (like a compiler plus some tests on AXMEDIS objects and estimation of some parameters such as the files complexity and required workload)
- **Rules List…** – Shows the list of rules inside the repository of the Rule Editor
- **Find Rule…** – Allows making queries to the rules repository of the Rule Editor
- **Debug:**
  - **Go** – Enter in the debug mode or if the script is stopped, continue execution until the script is finished, or a breakpoint is reached.
  - **Stop** – Stop the script execution and close the debug mode
  - **Step Over** – Executes the current line of the script, then pauses. This differs from the "Trace" command in that it will not step into functions and scripts that are called by the current line.
  - **Trace Into** – Executes the current line of the script, then pauses. This differs from the "Step" command in that if the current line calls a function, or another script, the debugger will trace into the called function or script.
- **Breakpoint:**
  - **Insert/Remove** – Set a breakpoint on the currently selected line of the script code. Every time the selected line is reached, the debugger will stop. Clear a breakpoint from the currently selected line of the script code.
  - **View list** – Open the debug window showing all breakpoints in the script code.

**Messages**
- **Last message** – Displays the last message sent by the AXMEDIS Workflow Manager
- **Messages List** – Displays the list of messages sent by the AXMEDIS Workflow Manager
DE3.1.2.2.6 – Specification of AXMEDIS Content Production

- Notify activity completion – it open the dialog for notifying the completion of the activity to the AXMEDIS Workflow Manager

**Window** (provided automatically by the MDI GUI)
- Cascade
- Tile Horizontal
- Tile Vertical
- Next – Activate the next document view
- Previous - Activate the previous document view
- Arrange Icons – Arrange the all minimised document views
- Close All – Close all document views
- Windows list

**Help**
- About – Information about the authors, version, etc

### 5.3.2 ToolBar Area

The toolbar area hosts a set of icon buttons that allows calling functions without accessing to the menu bar. The toolbar area is based on dockable toolbars and allows the dynamic customisation adding or removing sub-toolbars. For this end the editor provides sub-toolbars for:

- **Standard** functionalities such as:
  - New rule document – Create a new empty rule
  - Open from disk – Load a rule from disk
  - Save – Save a rule on disk
  - Cut
  - Copy
  - Paste

- **Debug**. It provides main controls for:
  - Start Debug
  - Stop Debug
  - Step Over
  - Trace Into
  - Add/Remove Breakpoint

### 5.3.3 Workspace Area

This is a resizable panel and includes a notebook control constituted of the following view items:

1. **Rule View** – In this area the structure of rule is displayed. It will be realised by using a Tree control that will permit to show and browse components according the rule XML schema. A dynamic popup menu will be available for a quick access to functions that will allow the quick management of items (edit and view metadata, delete,…). Appropriate icons will be also drawn in order to identify intuitively components of rule in the tree control view. In the following picture the structure of the Rule View area is depicted:
2. **Library view** – It is an on-line book that could be used as help by the user. It displays the set of functionalities provided by the Plugins installed and automatically detected by the editor. It is a tree control that permits to show and browse plugins module and the functionalities that they provide according to their profile.

The user can see the documentation associated with each selected function by interacting with each item of the tree by double clicking or accessing to a contextual popup menu. The Search function is available to save time in finding function, it works by using mime type of signature parameters as serching criteria. The selected documentation is displayed in the *Text/Html document view.*
5.3.4 Output Area
This is a text control where messages, textual description, errors, debugging info, alert, etc… are displayed.

5.3.5 Tools, Viewers and Editors
Some different types of tools and editors has been designed for visualizing and/or editing different types of document.

1. Javascript editing window – This is the window client where the user will be able to write the script code. It will be based on a multiline text control where it will be possible to edit the script. The textual editor will support some facilities such as:
   - Auto completion of words - a window listing possible completions for strings the user has typed
   - Syntax highlighting – keywords will be colourised
   - Brace highlighting
   - Folding/Hiding - making lines invisible or visible. It shows or hides a range of lines.
   - Multiple views - to have multiple views of the same Document. (Split view)
   - Breakpoint insertion/removal – to control the code in the debugging session
   - Visualisation of line numbers
2. **Text/Html document view** – This is the window for the visualisation of the documentation provided by the help on line. It is opened when the user double clicks on a voice of the index in the Library view or when the internal help is called. It provides functionalities for browsing TXT or HTML pages. For example, all the information related to the description of a function selected from the Library view are shown in such window.

3. **Selection Editor** - It is an internal editor that provides functionality for:
   a. Edit a selection
   b. Save/Load a selection
   c. Actualise the selection

For more details about the Selection editing see the DE3.1.2E Framework and Tools Specifications (Database and Gathering)

4. **Mapper Editor**
Mapper editor GUI will be an editor for Metadata Mapping AXEPTool. It will be the interface used to creates the map for incoming metadata translation. The GUI allows the user to decide which origin fields have to be converted in destination fields. The GUI will be invoked by the AXCP Editor.

For more details see document  DE3.1.2F Framework and Tools Specifications (AXEPTool and Progr. and Pub.).
5.3.6 Interactive Dialogs
The editor provides a set of dialogs for facilitate the editing of a rule. To this end, the following dialogs were designed:

1. **Configuration Dialog:** The AXCP Rule Editor allows accessing to the configuration dialog when it is necessary to modify the configuration file. The configuration Dialog is the same dialog used in the AXMEDIS Editor, it provides the list of modules and for each of them the set of parameters. The user can modify them by means of the “Add”, “Edit”, “Remove” functions.

   ![Configuration Dialog](image)

   The “Edit” function opens the “Set Param” dialog where it is possible to change values.

   ![Set Param Dialog](image)

2. **Header Rule Edit Dialog** – This is a tabbed dialog that allows filling fields of the header section. The dialog is designed as an OK/Cancel modal dialog in a notebook style with General, Producer and Comment tab where the list of items to edit are displayed.
3. **Dependency Edit Dialog** - This dialog allows filling fields for a dependency item. The dialog is designed as an OK/Cancel modal dialog and displays the list of item to edit. The dialog shows the list of plugin installed in order to facilitate the choice.

4. **Parameter Edit Dialog** - This dialog allows editing/filling fields for a parameter item. The dialog is designed as an OK/Cancel modal dialog and displays the list of items to edit.

5. **Schedule Edit Dialog** – This dialog allows filling/editing fields for a schedule item. The dialog is designed as an OK/Cancel modal dialog and displays the list of items to edit.
6. **Local Variables** – This is a page of the Debug dockable window that displays variables and instances of objects allocated by the script. They are displayed as tree list control with folding-unfolding capability for displaying the list of attributes of the object instance.

7. **Call Stack** – This a page of the Debug dockable window that displays stack of functions calls. It display the script name and the line of the call. Double clicking on an entry level of the stack allows focusing the view of the script where the corresponding call is located.

8. **Breakpoints** - This a page of the Debug dockable window that displays the list of breakpoints inserted in the scripts: each breakpoint is associated with the name of the script and relative line number and status (Enabled or Disabled). Double clicking on a breakpoint allows focusing the view of the script where the breakpoint is placed.

9. **Repository Rule List Dialog** - The Rule List command opens a rules list modal dialog displaying all rules stored in the repository of the AXCP Rule editor. In this window, the list of rules is organised in a table built on the following subset of metadata:
   - Rule Name
   - Rule Version
   - Author
• **Date of composition**
• **Rule ID (AXRID)**
• **Path**

The user can select a specific rule in order to open it in the rule editor. Such operation is possible by pushing the *Open* button or double clicking on the line of the chosen rule. The user visualizes the comment associated with rule by pushing the *View Comment* button, the comment is displayed in the *Output Area* of the Rule Editor. Otherwise the user cancels the operation by closing the dialog or pushing the *Close* button.

10. **Find** – This will be a common/standard find text no modal dialog where the user will put strings he wants to search in the text.

11. **Go To** – This will be an OK/Cancel no modal dialog where the user will put the number of the line where he wants to set the cursor

12. **Find Rule dialog** – The find rule command will open a dialog that will allow setting a query in order to search a specific rule inside the repository. The query will be built on the following set of metadata:
   • **Rule Name**
   • **Rule Version**
   • **Rule Type**
   • **Date (day, month and year)**

   Two logical operators will be available to make query: OR and AND.

   In event of some metadata missing, the query on the repository will be done with the available metadata. An empty query will be not executed, this will be controlled by activating the *OK* button when at least a metadata has been input.

   Clicking on the *OK* button will start the search in the rule repository. The *Cancel* button aborts the operation.
5.3.7 Debugging Rules (DSI)
The editor provides the debug mode for rule debugging. The debugging mode is possible using an instance of the Script Executor inside the AXCP Rule Editor. To this end the Script Executor is used in the Debugging mode and provides functionalities and data structure to:
- maintain the list of breakpoints to put in the code
- put traps in the code corresponding to breakpoints
- update call stack window
- call the rule engine and initialise it to the debugging mode
- manually control the execution of the script
- print output and internal errors when script runs.

The debug mode provides the following set of manual functions:
- **Start Debug/Next Breakpoint** – Enter in the debug mode or if the script is stopped, continue execution until the script is finished, or a breakpoint is reached.
- **Stop Debug** – Stop the script execution and close the debug mode
- **Step Over** – Executes the current line of the script, then pauses. This differs from the "Trace" command in that it will not step into functions and scripts that are called by the current line.
- **Trace Into** – Executes the current line of the script, then pauses. This differs from the "Step" command in that if the current line calls a function, or another script, the debugger will trace into the called function or script.
- **Skip** - Skips over current line without executing it. The script resumes the execution on the subsequent line.
- **Set Breakpoint** – Set a breakpoint on the currently selected line of the script code. Every time the selected line is reached, the debugger will stop.
- **Remove Breakpoint** - Clear a breakpoint from the currently selected line of the script code.
- **Remove All Breakpoint** - Clear all breakpoints in the script code.

The debug mode provides a set of icons to facilitate the usage and the interaction with the Script Editor:
- A red filled circle indicates an Enabled breakpoint
- A red empty circle indicates a Disabled breakpoint
- A yellow arrow indicates the line that will be executed.

5.3.8 User Commands and Reporting - AXMEDIS Workflow Manager interaction (DSI)
It provides communication support from/to the AXMEDIS Workflow Manager. Such services are divided in commands for the user and reporting.
- Messages coming from the AXMEDIS Workflow Manager:
  - Description of the work to perform
  - AXRID to associate with the rule to be prepared
  - Rule type
  - Schedule information
Some other information related to header of the rule (according to the XML schema)

- Reporting to the AXMEDIS Workflow Manager
  - Notification (end work with success)
  - Exception

Communication with the AXCP Rule Engine

- Commands to the AXMEDIS Rule Engine:
  - Activate rule
  - Install rule in the scheduler (xml file transfer)
- Notification, messages, files and exception returned by the AXMEDIS Rule Engine.

The communication between the AXCP Rule Editor and the Engine is based on the same protocol used by the Workflow Manager for communicating with the AXCP Rule Engine. It is Web Service-based.

5.3.9 External Procedures Profile Manager (DSI)

To enable AXMEDIS to be a flexible structure, which can be extended according to the specific user needs, plug-ins can be easily be integrated into the AXMEDIS framework. The plug-ins are handled by the Plug-In Managers (AXMEDIS Editor::Plug-In Manager and the Collector Engine::Collector Plug-In Manager).

The Plug-in Managers takes care about the installation, registration, and loading of plug-ins. Different kinds of plug-ins are supported, including:

- Data-manipulation plug-ins shall be able to modify AXMEDIS object structure, i.e. plug-ins which shall be able to delete or move existing components, insert new components, etc…
- Metadata show/manage plug-ins shall be used by Metadata View to adequately display and modify user-defined sets of metadata;
- Metadata production shall be able, through AXMEDIS object (and parts thereof) analysis, to produce metadata to be included into the object;
- Configuration plug-ins shall be used by AXMEDIS Editor Configuration Manager to manage and display specific configuration information;
- Workflow plug-ins which shall permit interaction of AXMEDIS Editor with AXMEDIS Workflow subsystem;
- Protection plug-ins, which contain protection algorithm enriching the set of those available for the Protection Processor;

To enable an effective management, a profile manager is responsible for the handling of the profile descriptions. This profile manager is very close to the Plug-In manager. It is responsible for loading the profiles from installed libraries. The relevant information includes:

- the category of the plug-in, e.g. content processing;
- the unique identifier of the plug-ins
- the signature of the plug-in
- data specific for the kind of plug-in
- the signature

As the external procedures profile is closely related to Plug-in Manager and the content processing algorithms details can be found in DE3-1-2-2-3 and in DE3-1-2-2-7, respectively.

5.4 Draft User Manual

5.4.1 Editing an AXCP Rule on AXCP Rule Editor

A content producer or manager wishes to create a content processing rule called AXCP Rule for manipulating/creating AXMEDIS multimedia objects.
MS Windows Firewall Alert at startup
The picture below shows the Windows Security Alert Dialog. To run AXCP Tools, please unlock the application clicking on the “Unlock” button. This operation allows AXCP tools to use network services and run properly.

Creating a new rule
To create a rule, the user starts the AXCP Rule Editor and from the opening screen creates a new Rule by selecting “New” from the tool bar or using the File menu (File → New) or using the keyboard shortcut “Ctrl+N” (see Screenshot 1). On requesting a new rule, the dialog box pops up and the user enters the name of the draft AXCP Rule and selects “OK” (see Screenshot 2).

After the rule name has been entered, the new rule is ready for editing with the ‘tree view’ used as a workspace and the editing dialogs for editing the rule details and making a rule schedule.
Loading an existing rule

Instead of creating a new rule, the user may wish to edit an existing draft rule. The user may have saved it as a file somewhere or saved it in the AXCP Rule Repository. By selecting ‘open’ or ‘Rule List’ or selecting a file in the history list (‘Recent Files…’), as seen in screenshot 4 and 5, the rule editor can load an existing draft rule from the Repository or elsewhere on the system.

**Header dialog**

This is the dialog that allows filling fields of the header section. The dialog is an OK/Cancel modal dialog in a notebook style with General, Producer and Comment tab where the list of items to edit is displayed.

**Note:** The AXRID field is read only and it is pre-filled with the identification code assigned by the rule editor.

**Schedule dialog**

This dialog allows filling/editing fields for a schedule item. The dialog is as an OK/Cancel modal dialog and displays the list of items to edit. The dialog allows setting the start date and time, the expiration date and time, and the conditions of periocity (how may times in term of unit such as days, week, month and so on).

**Dependency dialog**

This dialog allows filling fields for a dependency item. The dialog is an OK/Cancel modal dialog and displays the list of available plugins in order to facilitate the choice.
Open commands shows the command Open dialog

The Rule List command opens a rules list modal dialog displaying all rules stored in the repository of the AXCP Rule editor. In this window, the list of rules will be organised in a table built on the following subset of metadata:

- Rule Name
- Rule Version
- Author
- Date of composition
- Rule ID (AXRID)

The user can select a specific rule in order to open it in the rule editor. Such operation is possible by pushing the Open button or double clicking on the line of the chosen rule. The user can visualize the comment associated with rule by pushing the View Comment button, the comment is displayed the Output Area. Otherwise the user can cancel the operation by closing the dialog or pushing the Close button.

Editing a rule

The user can use the set of dialog and text editor to edit the AXCP rule (as shown in screenshots), and edit rule data such as:

- Parameter dialog for editing the attributes of a rule parameter
- Dependency dialog for editing the attributes of a AXMEDIS Plugin
- XML Selection Editor (XML viewer/editor for the XML representation of selections) and JavaScript Editor based on Scintilla Editor for text/javascript code editing. It provides full editing capabilities (copy, cut, paste, redo, undo, syntax highlighting, etc…), print preview, page setup and print functionalities, syntax highlighting, brace highlighting, folding/hiding of lines, breakpoint insertion/removal, visualisation of line numbers.
**Debugging Rule functionalities**

The editor provides functions to add/remove breakpoints (F9), start debug (F5), next breakpoint (F5), step over (F10) and step into (F11), stack calls monitoring, local variables visualization. In the output window a textual output provides internal errors or communication when script runs and during the debug session.

Main navigation interface of a Debug session and markers:

- A red filled circle indicates an Enabled breakpoint
- A red empty circle indicates a Disabled breakpoint
- A yellow arrow indicates the line that will be executed.

**Activating a rule**

The current version of the prototype allows installing a rule in the rule engine and notifying the completeness of the rule to the workflow manager. The activation can be done by using the **Activate** function in the Command menu or manually as described in the scenario 2.

**5.5 Configuration Parameters**

In this section the set of parameters regarding the configuration of the editor are listed. Such parameters are grouped into modules as reported below:

### 5.5.1 AXMEDIS Rule Editor

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>XML_RULE_PATH</td>
<td>it is the directory where the rule will be saved</td>
</tr>
<tr>
<td>XML_XSD_PATH</td>
<td>It is the directory where xml schema (XSD files) are stored</td>
</tr>
<tr>
<td>FRAME_SIZE</td>
<td>It is the information about the last width and height of the main frame</td>
</tr>
<tr>
<td>FRAME_POSITION</td>
<td>It is the information about the last position (x,y) of the main frame</td>
</tr>
<tr>
<td>FILE_HISTORY</td>
<td>It is the list of recent rule documents</td>
</tr>
</tbody>
</table>

### 5.5.2 Workflow Manager

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
</table>
5.5.3 AXMEDIS Plugin Manager

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLUGINS_PATH</td>
<td>It is the directory where the DLL of plug-ins with their profiles (workflow, adaptation, descriptor and fingerprint estimators) are stored.</td>
</tr>
</tbody>
</table>

5.5.4 AXMEDIS Database

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>The user name for logging into Database</td>
</tr>
<tr>
<td>passwd</td>
<td>The password for logging into Database</td>
</tr>
<tr>
<td>LoaderWSEndPoint</td>
<td>It is the URL for the loader</td>
</tr>
<tr>
<td>HTTPPath</td>
<td>It is the HTTP path</td>
</tr>
<tr>
<td>UploadPath</td>
<td>It is the Upload path</td>
</tr>
<tr>
<td>SaverWSEndPoint</td>
<td>It is the URL for the saver</td>
</tr>
</tbody>
</table>

5.5.5 AXMEDIS Rule Engine

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>gatewayUrl</td>
<td>it is the URL of the AXCP Rule Scheduler/GRID</td>
</tr>
</tbody>
</table>

5.5.6 AXMEDIS Selection

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAIN_QUERY_SUPPORT_WSDL</td>
<td>It is the URL of the WSDL for using the Main Query Support</td>
</tr>
<tr>
<td>SELECTION_ARCHIVE_WSDL</td>
<td>It is the URL of the WSDL for using the Selection Archive</td>
</tr>
</tbody>
</table>

Example of Configuration file

```xml
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!--Sample XML file generated by XMLSPY v2004 rel. 3 U (http://www.xmlspy.com-->
  <Module category="AXMEDIS_RULE_EDITOR">
    <Parameter name="FILE_HISTORY" type="string">C:\incoming\Nuova cartella\Rules\resizing_rule.xml;C:\incoming\Nuova cartella\Rules\multigeneration.xml;C:\Axmedis\axmedis\Applications\ruleeditor\bin\win32\rt_test_rule.xml;\MASTER\ex-wedelmusic\localdistributor\htdocs\axdb-share;C:\Axmedis\axmedis\Applications\ruleeditor\bin\win32\ilabs-lobster.xml;C:\PictureAndDoc.xml;C:\Noname.xml;C:\queryTest.xml;C:\axexamples\ruleeditor\Rules\raw_multigeneration.xml; </Parameter>
    <Parameter name="XML_XSD_PATH" type="string">./ </Parameter>
    <Parameter name="XML_RULE_PATH" type="string">./ </Parameter>
    <Parameter name="FRAME_SIZE" type="string">738:1024 </Parameter>
    <Parameter name="FRAME_POSITION" type="string">0:0 </Parameter>
  </Module>
  <Module category="AXMEDIS_PLUGIN_MANAGER">

### 6.1 General Description of the Module

In this section, the specification of the AXCP Rule Engine will be discussed. As already discussed, the content processing activity (production, protection and publication on AXEPTool) will be based on a unified and shared solution. In these terms, the AXCP Rule Engine will play the role of:

- AXMEDIS Compositional/Formatting Engine
- AXEPTool Loading Tool Engine
- AXEPTool Publication Tool Engine
- AXEPTool P2P Active Selection Engine
- The Protection Tool Engine

By delegating the processing activity to a single rule engine seems to be not the best solution since the amount of work and the dimension of data that the engine will have to manage is high. The main idea is to design a distributed environment of engines for the AXMEDIS object processing based on GRID. This solution will maintain advantages of a unified solution and allow enhancing the capabilities of the AXMEDIS content processing area by running rules in parallel.

According to the UML diagram, the AXCP Rule engine will be divided in two main components:

- **Rule Scheduler (Server Side)** – It consists of the Scheduler and Dispatcher. It performs the operations of rule firing, rule executor discovering and management, rules dispatching, communication with the AXMEDIS environment, etc....

**AXMEDIS Project**
• **Rule Remote Executor (Client Side)** – It is the executor of rules and consists of a script engine based on JavaScript (JS) SpiderMonkey released by Mozilla. It receives the JavaScript code associated with rule and performs the necessary operations for: Script preparation, JS Engine initialisation, JS Engine running script.

The Grid infrastructure is realised by means P2P technology. For these reason both the Rule Scheduler and the Rule Executors host a P2P communication support.

**Compositional/Formatting Engine**

*To be taken as an example of others AXMEDIS Engine for Rules*

From the compositional/formatting engine it is possible to protect the Objects on demand by passing from the WF manager that may host some specific flow rules to activate on the basis of messages of the Protection Tool Engine.

### 6.2 Rule Scheduler

The Rule Scheduler is the application involved in the rules engines management. It plays the role of server in the distributed environment. It will be a multithread application and will be developed by using the wxWidgets ver. 2.4.2 library. This should allow having a multiplatform rule scheduler.
Referring to the picture, it is constituted of following parts:

**6.2.1 Scheduler Command Manager**

The Scheduler Manager is the main application and provides the interface to the Scheduler GUI. The main provided functionalities are:

- Load/Save the configuration file.
- Initialisation of the scheduler
- Starting the scheduler
- Stopping the scheduler
- Exporting the list of rules and remote executors
- Browsing the list of jobs/rules and remote executors
- Performing backup of current status (list of rules)
- Performing the restore of the last list of rules
- Load/Install rules
- Providing commands for managing, controlling and monitoring the execution of rules and the activity of remote executors.
- Logs and reports management

The Scheduler Manager manages the configuration parameters stored in a “configuration.xml” file. The set of parameters contains information about:

- **Backup Time** - Backup interval for logging the set of submitted rule and tracing operations. It is expressed in minutes.
- **Time Out** - Time out on client activity. It is expressed in seconds.
- **Time Resolution** - Time Resolution of the scheduler. It is expressed in seconds.
- **Refresh Time** - Time Resolution for discovering new rule executors
• **Rules Path** - Rule Repository Path
• **Log Path** - Log Repository Path
• **Profile Path** - Executor Profile Repository Path
• **Backup Path** – The path where the scheduler periodically saves the current rules list.

The management of configuration parameters is done by using the AXMEDIS Configuration Manager.

### 6.2.2 Engine command and reporting (AXMEDIS Workflow Manager interaction)

It provides the communication and the interaction layer with the AXMEDIS Workflow Manager and to external applications such as the AXMEDIS Rules Editor. It is based on Web Service (GSOAP) and Workflow PlugIn. This module provides communication functionalities and allows managing:

- **Commands coming from the AXMEDIS Workflow Manager:**
  - *Run rule(AXRID, arguments, when)* – Ask for a running of a rule specified by means the AXRID, this command could override the arguments value of the rule by sending the xml descriptions about the *arguments* section(according to the XML schema) and could specify when the rule has to be run by overriding the *schedule*. If the command does not override the arguments the rule will be executed with the current arguments. If the command does not override the schedule, the rule will be executed immediately. Also all other combinations of overriding will be considered.
  - *Activate rule(AXRID)* – Switch the status of the rule specified by means the AXRID in the “ACTIVE” status
  - *Deactivate rule(AXRID)* - Switch the status of the rule specified by means the AXRID in the “INACTIVE” status
  - *Remove rule(AXRID)* – Remove the rule specified by means the AXRID from the Scheduler
  - *Pause rule(AXRID)* – Put the rule specified by means the AXRID in the “PAUSE” status
  - *Suspend rule(AXRID)* - Put the rule specified by means the AXRID in the “SUSPENDED” status for a specific time.
  - *Resume rule(AXRID)* – Resume the rule specified by means the AXRID
  - *Kill rule(AXRID)* – Stop the running of the rule specified by means the AXRID
  - *Install and activate rule (rule xml file)* – Install a new rule in the Scheduler by sending the XML file.
  - *Get list of rules* – Request the list of AXRIDs related to rules currently in the scheduler.
  - *Get logs(AXRID)* – Request the current action log generated by the Rule Scheduler. The action log will be pre-filtered to make available to the workflow an action log that is structured per each rule.
  - *Get rule status(AXRID)* – Request the current status of the rule specified by means the AXRID and the start time if rule is running or the next running time if it is not
  - *Get xml rule(AXRID)* - Request the XML file of the rule specified by means the AXRID

- **Reports, messages and files returned to the AXMEDIS Workflow Manager:**
  - Error notification (failure messages)
  - Complete rule notification
  - Log of the current activity
  - List of AXRIDs related to the currently scheduled rules
  - XML file of Rule
  - Rule status (current status plus schedule information)

### 6.2.3 Communication with the AXMEDIS Rule Editor

- **Commands coming from the AXMEDIS Rule Editor:**
  - Get list of rules
  - Activate rule
  - Deactivate rule
  - Remove rule
o Install rule in the scheduler (xml file transfer)
   o Get Rule

The communication between the AXCP Rule Editor and the Engine is Web Service based on the same protocol used by the Workflow Manager. This allows avoiding duplications.

6.2.4 Internal Scheduler

The internal scheduler is the manager of active rules. It has to detect, fire, launch and manage the execution of a rule. During its activity, the internal scheduler has to:

1. preserve the scheduled work from interruption of service (crash of the application) giving the possibility to restore the last status of activity
2. manage and update the list of rules to be scheduled and their status
3. manage and update the list of available rule executors
4. notify to the AXMEDIS Workflow Manager messages due to:
   • errors during the phase of rule association with an executor
   • errors due to the launching phase
   • errors during the rule execution on remote executor.
   • errors due to the time out deadline missing (the executor did not respond to request)

To this end, the functionalities provided by the rule scheduler are:

• Select from the internal scheduled rules the rule that matches conditions for the execution. This is performed by:
  o checking the execution time and date
  o receiving an immediate run command from the AXMEDIS Workflow Manager
• Modify and set the time resolution for the control of rules execution
• Add a new submitted rule in the list of jobs
  o Loading the corresponding rule xml file from the repository directory
  o Extracting the metadata for scheduling
  o Generating and assigning a Job Id to the rule
• Remove a rule from the list of jobs
• Run a rule on demand
• Reschedule a rule (by overriding the schedule information)
• Override rule arguments (by replacing the current arguments)
• Check expiration conditions of a rule
• Provide the list of jobs/rules
• Update firing conditions of a periodic rule
• Browse the list of jobs/rules
• Modify the status of rules
• Remove an executor from the list of executors
• Provide the list of executors
• Browsing the list of executors
• Save periodically on disk a backup copy of the list of jobs
• Restore the last status by loading the backup copy of the list of jobs
• Route messages coming from the dispatcher and the remote executors to the AXMEDIS Workflow Manager

Rule Life Cycle

The life cycle of rule represents the evolution of a rule from the activation to its completion. The evolution is strictly linked to the activities performed by the scheduler, the dispatcher and the executor and it can be described by means of a status attribute. The status of a rule assumes the following values:

1. **Active** – The rule is waiting for the execution
2. **Inactive** – The rule is not executed
3. **Failure** – An error occurred during the execution or control of rule. The execution is blocked and the executor is released.
4. **Launching** – The rule is associated with a remote executor.
5. **Delayed** – The launch of rule has been delayed. Available executors are temporary busy with another rule.
6. **Running** – The rule is running on a remote executor
7. **Pause** – The run of rule has been stopped temporarily
8. **Suspended** – The run of rule is suspended by defining a temporal interval. The time unit is second.
9. **Complete** – The run is finished

State Diagram for an AXCP rule

The general evolution of the rule status is depicted in the State Diagram representation, whereas the description of each transition is reported in the following.

**Complete to Active Transition** – The transition from COMPLETE to ACTIVE status is performed if the rule has to be executed periodically. In this case, the rule is re-submitted to the scheduler and its run-conditions are updated on the basis of the specified period.

**Complete to Inactive Transition** – The transition from COMPLETE to INACTIVE status is performed when the rule has to be executed once. In this case, the rule is ready to be removed from the scheduler or to be modified by means of the Rule Editor or to be run on demand.

**Active to Launching** – The transition from ACTIVE to LAUNCHING status is performed when the scheduler fires a rule. The rule has to be associated with a remote executor.

**Launching to Running Transition** – The transition from LAUNCHING to RUNNING status is performed when a rule is running on the remote executor.
Launching to Delayed Transition – The transition from LAUNCHING to DELAYED status is performed when the executor that could run the rule is busy. The rule is placed temporarily in a delay queue to be run when the executor will be ready.

Delayed to Running Transition – The transition from DELAYED to RUNNING status is performed when the remote executor is ready to run the rule.

Launching To Failure Transition – The transition is performed when during the rule check operation, the rule profile does not match any available executor profiles.

Running to Failure Transition – The transition from RUNNING to FAILURE status is performed if the following conditions occur:
- when during the execution of rule the corresponding rule executor sends a run-time error message.
- when during the execution of the rule, the executor does not respond to sever call (Time out).

Running to Complete Transition – The transition from RUNNING to COMPLETE status is performed when the execution of rule is successfully completed.

Running to Pause Transition – The transition from RUNNING to PAUSE status is performed when a pause rule request comes from the Scheduler. The status of PAUSE can be conditioned by deadline condition.

Pause to Running Transition – The transition from PAUSE to RUNNING status is performed when a resume rule request comes from the Scheduler.

Failure to Inactive Transition – The transition from FAILURE to INACTIVE status is performed when a disable rule request comes from the AXMEDIS Workflow Manager or from the Rule Editor.

Failure to Active Transition – The transition from FAILURE to ACTIVE status is performed when a disable rule request comes from the AXMEDIS Workflow Manager or from the Rule Editor.

Suspended to Failure Transition – The transition from SUSPENDED to FAILURE status is performed when the suspension misses the deadline condition.

Running to Suspended Transition – The transition from RUNNING to SUSPENDED status is performed when a rule suspension request comes from the Scheduler. The status of SUSPENDED is conditioned by a deadline condition (e.g. a temporal interval).

Suspended to Running Transition – The transition from SUSPENDED to RUNNING status is performed when a resume rule request comes from the Scheduler. Since the status of SUSPENDED can be conditioned by deadline condition, a rule is automatically resumed by the scheduler when the deadline condition is matched.

Jobs as Rules
From the scheduler point of view, a rule is a job to be executed. Each job is described by using the metadata contained in the Header, Schedule and Definition section of the rule.
Jobs are organised in a table, called Table of Jobs. Such table is monitored by the internal scheduler periodically to detect the rule to be fired. A periodic backup of the table is performed to guarantee a certain degree of reliability in case of critical problems that could require to restart the scheduler. The backup copy will permit to restore the last status of the scheduler.

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rule Name</td>
<td>The name of rule. It comes from the corresponding data in the Header section of the rule</td>
</tr>
</tbody>
</table>
### Rule Version
The version of rule. It comes from the corresponding data in the Header section of the rule.

### Rule Type
The type of rule. It comes from the corresponding data in the Header section of the rule.

### Start Time
The start time of execution. It comes from the corresponding data in the Schedule section of the rule.

### Start Date
The start date of execution. It comes from the corresponding data in the Schedule section of the rule.

### Periodicity
The name of rule. It comes from the corresponding data in the Schedule section of the rule.

### Expiration Time
The expiration time of job life. It comes from the corresponding data in the Schedule section of the rule.

### Expiration Date
The expiration date of job life. It comes from the corresponding data in the Schedule section of the rule.

### Executor ID
It is the identifier of the current executor associated with the rule by the Dispatcher.

### N° of Run
Number of times that the rule has been run.

### Job ID
Identifier associated with the rule by the scheduler.

### Profile
List of dependencies (AXMEDIS Plug In, external tools, etc…). It comes from the Uses data in the Definition section of the rule.

### URL
The complete path of the rule xml file.

### 6.2.5 Rule Scheduler User Interface
The Scheduler GUI will be the main window that allows the interaction with the Scheduler. It is constituted of:

1. A menu bar
2. Two main areas where the list of rules and the list of remote executors are displayed.
3. A status bar where the current clock and the current date are displayed.

#### Menu bar
- It provides the access to the following set of functions:
  1. **Program**
     a. **Add Rule** – It allows to load rules and install into the scheduler
     b. **Launch scheduler** - Start the scheduler activity.
     c. **Stop scheduler** - Stop the scheduler activity.
     d. **Backup** - Backup Copy of the last jobs list.
     e. **Restore** – Restore a backup copy
     f. **Minimize** - It reduces at icon on the taskbar.
     g. **Exit** - Close the application.
     h. **Start Grid Peer Functions** – It starts the components for P2P network access

<table>
<thead>
<tr>
<th>AddRule</th>
<th>Ctrl+R</th>
</tr>
</thead>
<tbody>
<tr>
<td>Launch scheduler</td>
<td>Ctrl+L</td>
</tr>
<tr>
<td>Stop scheduler</td>
<td>Ctrl+S</td>
</tr>
<tr>
<td>Backup</td>
<td>Alt+B</td>
</tr>
<tr>
<td>Restore</td>
<td>Alt+R</td>
</tr>
<tr>
<td>Minimize</td>
<td>Alt+M</td>
</tr>
<tr>
<td>Exit</td>
<td>Alt+Y</td>
</tr>
<tr>
<td>Start Grid Peer functions</td>
<td>Ctrl+H</td>
</tr>
</tbody>
</table>

#### 2. Settings
- Preferences - Open an editable dialog with the set of configuration parameters.

#### 3. View
- Refresh – Update the list of jobs and list of remote executors.
b. **Arrange** – Repainting modes of tables in the main frame
   i. **Top** – It shows only the top table (Table of rules)
   ii. **Bottom** – It shows only the bottom table (Table of executors)
   iii. **Vertical** – It shows tables vertically
   iv. **Horizontal** – It shows tables horizontally

c. **Rule Properties**... - Open a Rule Properties dialog.

d. **Executor Profile**...- Open an Executor Profile dialog.

e. **Logs**...- Open a dialog to show the list of log messages

f. **Debug Monitor**... A dialog for debug purpose

<table>
<thead>
<tr>
<th>Function</th>
<th>Shortcut</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rule Properties</td>
<td>Ctrl-R</td>
</tr>
<tr>
<td>Executor Profile</td>
<td>Ctrl-E</td>
</tr>
<tr>
<td>Logs</td>
<td>Alt-L</td>
</tr>
<tr>
<td>Debug Monitor</td>
<td>Alt-O</td>
</tr>
</tbody>
</table>

4. **Commands**

   a. **Enable Rule** - Put in the “ACTIVE” status the current selected inactive rule.
   b. **Disable Rule** - Put in the “INACTIVE” status the current selected active rule.
   c. **Kill Rule** - Kill the current execution of the current selected rule.
   d. **Pause Rule** - Put in pause the execution the current selected rule.
   e. **Resume Rule** - Resume the execution of the current selected rule.
   f. **Suspend Rule**... - Open a dialog to edit the temporal interval for rule resuming and then suspend the current selected rule.
   g. **Remove Rule** – Remove the rule from the list of rules

<table>
<thead>
<tr>
<th>Function</th>
<th>Shortcut</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Rule</td>
<td>Alt-N</td>
</tr>
<tr>
<td>Disable Rule</td>
<td>Alt-D</td>
</tr>
<tr>
<td>Kill Rule</td>
<td>Alt-K</td>
</tr>
<tr>
<td>Pause Rule</td>
<td>Alt-P</td>
</tr>
<tr>
<td>Resume Rule</td>
<td>Alt-S</td>
</tr>
<tr>
<td>Suspend Rule</td>
<td>Alt-L</td>
</tr>
<tr>
<td>Remove Rule</td>
<td>Ctrl-M</td>
</tr>
</tbody>
</table>

5. **?**

   a. **Help** - Open the On Line help.
   b. **About** - Open a dialog with credits.

All this functionalities are also accessible by means shortcuts.
### Rules/Jobs Table

It is the area where scheduled rules are displayed. It is a list control constituted of a set of columns where the following list of metadata are displayed:

- **Rule name** – the name of the rule
- **Rule version** – the version of rule
- **Rule status** – the current status of rule
- **Rule ID** – the identifier of rule
- **Executor ID** – the identifier of the executor associated with rule
- **Start Time** – the time to fire the rule
- **Start Date** – the date to fire the rule
- **Periodicity** – the periodic attribute
- \textit{N° Runs} – the number of time the rule was fired.

<table>
<thead>
<tr>
<th>Name</th>
<th>Version</th>
<th>Status</th>
<th>ID</th>
<th>Executor ID</th>
<th>Start Date</th>
<th>Start Time</th>
<th>Periodicity</th>
<th>N° Runs</th>
</tr>
</thead>
</table>

The following functionalities are provided by means a contextual popup menu:
- Ordering rules alphabetically by name
- Ordering rules by start running time
- Ordering rules by ID

\textbf{Remote Executors Table} - It is the area where remote executors are displayed. It is a list control constituted of a set of columns where the following list of metadata is displayed:
- \textit{Name} - Computer Name
- \textit{IP} - IP address
- \textit{CPU} - CPU & Clock
- \textit{OS} - OS & Version
- \textit{Ping} – The network capabilities in term of transmission time.
- \textit{HD Space} – The space available on the disk of the executor
- \textit{Status} – The status of the executor
- \textit{Rule ID} – The ID of the running rule
- \textit{Executor ID} – The Id of the executor assigned by the scheduler
- \textit{Start Time} – At what time the run is started.

<table>
<thead>
<tr>
<th>Name</th>
<th>IP</th>
<th>CPU</th>
<th>OS</th>
<th>Ping</th>
<th>HD Space</th>
<th>Status</th>
<th>ID</th>
<th>RuleID</th>
<th>Start Time</th>
</tr>
</thead>
</table>

The following functionalities are provided by means a contextual popup menu:
- Ordering executors alphabetically by computer name
- Ordering executors by ID
Auxiliary dialogs
The Scheduler GUI is supported by the following set of dialogs:

Rule Properties Dialog – It is an editable no modal dialog where the properties of the selected rule are displayed. Some of these properties are extracted from the XML file associated with rule.

Executor Profile Dialog - It is a not editable no modal dialog where the properties of the selected executor are displayed. Some of these properties are extracted from the executor profile.

Logs Dialog – This dialog allows viewing the logs of scheduler activity.

Suspend Rule Dialog – It is an editable no modal dialog where the user puts the time for the suspension.

Preferences Dialog – It is a tabbed dialog that allows editing settings parameters regarding the scheduler activity (Scheduler settings) and the GRID support (GRID settings).

Scheduler settings – It consists of a set of configuration parameters contains settings about:
- **Backup Time** - Backup interval for logging the set of submitted rule and tracing operations. It is expressed in minutes.
- **Time Out** - Time out on client activity. It is expressed in seconds.
- **Time Resolution** - Time Resolution of the scheduler. It is expressed in seconds.
- **Refresh Time** - Time Resolution for discovering new rule executors
- **Rules Path** - Rule Repository Path
- **Log Path** - Log Repository Path
- **Profile Path** - Executor Profile Repository Path
- **Backup Path** – The path where the scheduler periodically saves the current rules list.
Grid settings – It provides a set of settings to setup the communication support. It allows to define the number of ports to use when receiving file, messages, sending files, responding to the discovering request. It allows also to define IPs of LANs to use when the scheduler performs the discovering of peers.

6.2.6 Dispatcher of the Rule Scheduler
The main role of the dispatcher is to:
- associate a remote executor with the rule to be run
- engage the selected remote executor
- launch the execution of rule on the remote executor
- monitoring the status of remote executors
- managing the possible errors messages and notifications coming from executors
- creating logs and tracing the activity of each remote executor involved in the execution of a rule
- discovering new remote executor
- requesting and receiving the profile from remote executors

Remote Executors
A remote executor is the virtual image on the scheduler side of a real machine equipped with the rule executor. Knowing the availability and capabilities of a remote executor is mandatory to identify the machine that will execute the rule. To this end, the association of executors with rules is based on the list of available remote executors (computer) and their profiles. Such list is persistent and it is managed at run-time. Each remote executor belonging to the list is described by means of internal attributes (managed by the scheduler) and a profile that is sent by each real executor during the discovery and refreshing phase. The profile contains a set of metadata that describes the capabilities of the remote executor (see Section 6.9.6).
<table>
<thead>
<tr>
<th>Attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Current Status</td>
<td>It provides the status of the executor</td>
</tr>
<tr>
<td>Executor ID</td>
<td>Identifier of the executor</td>
</tr>
<tr>
<td>Profile</td>
<td>It is the set of information related to:</td>
</tr>
<tr>
<td></td>
<td>1. Identity of the executor (computer name, IP address, location, etc…)</td>
</tr>
<tr>
<td></td>
<td>2. Computational capabilities: (CPU, RAM, Clock, etc…)</td>
</tr>
<tr>
<td></td>
<td>3. Functionalities that the executor provides:</td>
</tr>
<tr>
<td></td>
<td>• AXMEDIS Plug-In installed (For each plug in the name and version are</td>
</tr>
<tr>
<td></td>
<td>provided).</td>
</tr>
<tr>
<td></td>
<td>• External tools Plug-In installed For each plug in the name and version</td>
</tr>
<tr>
<td></td>
<td>are provided).</td>
</tr>
</tbody>
</table>

To realise that, the dispatcher is divided in four main components.

**Resource Controller** – It periodically controls and refreshes the availability of remote executors in the network of AXMEDIS factory. To this end, it performs the following activities:
- discovering new remote executors
- requesting profiles of remote executors
- refreshing and managing the list of available remote executors (adding a new discovered executor, remove an executor from the list, loading the profile)
- generating and assigning an unique Executor ID (process Id) with the remote executor
- initialising the remote executor (by sending the Executor ID, the port number to use for sending messages to the Rule Monitor)
- managing and updating the status of each remote executor.
- generating an error in case of time out or deadline missing (the remote executor did not respond to a request within a time interval specified by a time out)

**Optimizer** – It receives rules to be launched. They are put in an internal queue that includes rules to be associated with a remote executor. The choice of an executor is performed by checking the rule profile with the best profile among available remote executors. If all available remote executors do not match the profile of rule, the association fails, the status of rule is set to “Failure” and an error message is generated and sent to the internal scheduler. If all remote executors matching the profile of the current rule are running different rules, the launch of the current rule is delayed and the rule is maintained in the internal queue of rules waiting for an available executor.

Future version of the optimizer will include optimisation algorithm based on Deadline monotonic algorithm that will improve the scheduler capability.

**Rule Launcher** – The rule launcher:
1. sends commands generated by the scheduler (kill, pause, run, resume) to remote executors
2. engages the remote executor associated with the rule and launch the execution of rule. If the engaging fails an launch error is generated.

To this end, the rule launcher provides functionalities for:
- communicating with the remote executor (by sending and receiving messages and commands)
- transferring the rule to the remote executor
- communicating errors messages to the internal scheduler if the launch phase fails
- tracing the commands and controls sending to remote executors by updating an activity log file

**Rule Monitor** – It monitors persistently the execution of rules by:
- listening to messages and notifications coming from remote executors
- interpreting messages
- managing the log file and trace the activity of each rule executor (by reporting all messages and notifications in input)
- communicating the status of a rule to the internal scheduler for updating
• routing possible errors messages and notifications to the internal scheduler
To this end, the rule monitor provides functionalities for:
• communicating with the remote executor (by receiving messages and notifications)
• parsing messages of executors
• providing and managing a queue of input messages
• updating log files associated with each remote executor for each message or notification received
• routing errors and messages to the internal scheduler coming from executors

6.2.7 Grid Peer Interface
It is the interface to the Grid Peer. It provides functionalities for:
• Sending message to a peer
• File transfer to a peer
• Discovering peers
• Engaging/Launching a peer
• Managing messages coming from other peers

6.2.8 Grid Peer
It provides the support for the distributed system management. It is based on TCP/UDP socket and is
constituted of the following components:
• Peer Explorer – It provides functionalities and support for querying the presence of other peers. It is
  based on UPD broadcast messages.
• Peer Communicator – It provides functionalities and support for communicating with available
  peers (already discovered). It is based on TCP connection.
• Peer File Transfer – It provides functionalities and support for transferring file to a selected peer. It
  is based on TCP connection.
• Peer Event Consumer – It provides functionalities and support for handling events of
  communication, file transfer and discovering.

These components are used singularly and independently. It was developed in C++ with STL and
WindowsSocket library.

6.2.9 Structure of messages exchanged between Scheduler and Remote Executor
Messages exchanged between the Scheduler and the Remote Executor can be different types and grouped in
two set of messages: (i) from Scheduler to Rule Executor and (ii) from Rule Executor to Scheduler.

Messages from Scheduler to Rule Executor:
1. Command – the message is a specific command

Messages from Rule Executor to Scheduler:
2. Notification – the message is a notification
3. Error – the message reports an error
4. Response – the message is a response to a request or a command

The main idea is to have a common message structure that allows covering all these types. In addition, to
guarantee a fast delivery on the network, messages are light. To this end, they are based on a formatted text
and structured according to the following EBNF formalisation:

<message> := <Sender ID> '#'<Type_Msg>

<Sender ID> := <string>
<Type_Msg> := <CMD_MSG> | <REQ_MSG> | <NOTIFY_MSG> | <ERR_MSG> | <RESP_MSG>
<CMD_MSG> := ‘COMMAND#’<ID_MSG>‘#’<command>
<command> := RUN | KILL | PAUSE | RESUME | GET <request> | SET <attribute> <value>
:request> := PROFILE | STATUS | ID
<attribute> := ID | …
<value> := <string>

<NOTIFY_MSG> := ‘NOTIFICATION#’<what notified>
<what notified> := ‘END PROCESS’ | <msg>
<msg> := ‘MSG’<string>

<ERR_MSG> := ‘ERROR#’<error from>‘#’<error description>
<error from> := ‘RULE’ | ‘EXECUTOR’
<error description> := <error code> | <string>

<RESP_MSG> := ‘RESPONSE#’<to msg>‘#’<response argument>
<response argument> := <status> | <executor ID> | ‘CMD OK’
<to msg> := <ID_MSG>

<ID_MSG> = <timestamp>

Where:
<timestamp>: it indicates the generation time of a message and allows indexing a message. It could be used as reference to link a response message to command messages and to monitor the activity of the rule executor.

(Sender ID): it indicates the identifier of the sender. By default, the ID of the Scheduler is ‘0’, whereas for all rule executors will be the Executor ID

<error code>: it reports the code of the error

Example 1:
The scheduler requests the profile to a rule executor by means the message:

0#COMMAND#12:00:00 pm#GET PROFILE

where:
• ‘0’ is the sender ID associated with the scheduler (server).

Example 2:
The scheduler sends to the rule executor its Executor ID:

0#COMMAND #12:20:00 pm#SET ID 34

The scheduler requests the value of status to the executor identified by “34” by means of the message:

0#COMMAND #12:20:00 pm#GET STATUS

The rule executor “34” responds to the request by means of:

34#RESPONSE#12:20:00 pm#’value of status’

where:
• ‘34’ is the sender ID associated with the Executor ID of the rule executor.

Example 4:
The rule executor ‘34’ sends to the scheduler:
DE3.1.2.2.6 – Specification of AXMEDIS Content Production

- a message generated by the rule:
  
  34#NOTIFICATION#MSG "AXMEDIS Database connection error"

- a run time error
  
  34#ERROR#EXECUTOR#"Disk Full" or 34#ERROR#EXECUTOR#001

where ‘001’ could be for instance the error code associated with “Disk Full”

- an end process notification
  
  34#NOTIFICATION#END PROCESS
6.2.10 Rule Scheduler Class Diagram

Class diagram of Scheduler GUI

Class diagram of Internal Scheduler
6.3 Configuration Parameters

In this section the set of parameters regarding the configuration of the rule scheduler are listed. Such parameters are grouped into modules as reported below:

### 6.3.1 AXMEDIS Rule Scheduler Frame

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>FRAME_SIZE</td>
<td>it is the frame size information</td>
</tr>
<tr>
<td>FRAME_POSITION</td>
<td>it is the frame position information</td>
</tr>
<tr>
<td>XML_XSD_PATH</td>
<td>It is the directory where xml schema (XSD files) are stored</td>
</tr>
</tbody>
</table>

### 6.3.2 AXMEDIS Rule Scheduler Settings

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>BACKUP_TIME</td>
<td>It is the interval of Backup</td>
</tr>
<tr>
<td>RESOLUTION</td>
<td>It is the resolution in terms of time</td>
</tr>
</tbody>
</table>
### 6.3.3 AXMEDIS Grid Support Settings

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERV_PORT</td>
<td>It is the value of the port used by the Grid Interface</td>
</tr>
<tr>
<td>SERV_PORT2</td>
<td>It is the value of the port used by the Grid Interface</td>
</tr>
<tr>
<td>SERV_PORT3</td>
<td>It is the value of the port used by the Grid Interface</td>
</tr>
<tr>
<td>SERV_PORT4</td>
<td>It is the value of the port used by the Grid Interface</td>
</tr>
<tr>
<td>SERV_PORT5</td>
<td>It is the value of the port used by the Grid Interface</td>
</tr>
<tr>
<td>DEFAULT_NET</td>
<td>It is the list of IP address</td>
</tr>
</tbody>
</table>

### 6.3.4 AXMEDIS Plugin Manager

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLUGINS_PATH</td>
<td>it is the frame size information</td>
</tr>
</tbody>
</table>

### 6.3.5 WORKFLOW

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>workflowUrl</td>
<td>it is the URL for workflow plugin</td>
</tr>
<tr>
<td>gatewayUrl</td>
<td>it is the gatewayURL for workflow plugin</td>
</tr>
</tbody>
</table>

In the following an example of configuration file:

```xml
<?xml version="1.0" encoding="UTF-8" standalone="no" ?>
<Configuration xmlns="http://www.axmedis.org/configuration">

  <Module category="" id="AXMEDIS_RULE_SCHEDULER_FRAME">
    <Parameter name="FRAME_SIZE" type="string">738:1024</Parameter>
    <Parameter name="FRAME_POSITION" type="string">0:0</Parameter>
    <Parameter name="XML_XSD_PATH" type="string">C:\Axmedis\axmedis\Applications\rulescheduler\bin\win32</Parameter>
  </Module>

  <Module category="" id="AXMEDIS_RULE_SCHEDULER_SETTINGS">
    <Parameter name="BACKUP_TIME" type="string">30</Parameter>
    <Parameter name="RESOLUTION" type="string">5</Parameter>
    <Parameter name="TIME_OUT" type="string">60</Parameter>
    <Parameter name="DISCOVERING" type="string">2</Parameter>
    <Parameter name="LAUNCHING_TIME_OUT" type="string">3600</Parameter>
    <Parameter name="RULES_PATH" type="string">.\Rules</Parameter>
    <Parameter name="PROFILES_PATH" type="string">.\Profiles</Parameter>
    <Parameter name="BACKUP_PATH" type="string">.\Backup</Parameter>
    <Parameter name="LOGS_PATH" type="string">.\Logs</Parameter>
  </Module>

  <Module category="" id="AXMEDIS_GRID_SUPPORT_SETTINGS">
    <Parameter name="SERV_PORT" type="string">3000</Parameter>
  </Module>

</Configuration>
```
6.4 Technical and Installation information

| References to other major components needed | The AXCP Grid Node works in conjunction with the AXCP Rule Scheduler. |
| Problems not solved | The current version is not equipped with a system to limit the request of CPU. So it could happen that the run of a rule requires 100% of CPU. This will be solved in the next version. |
| Configuration and execution context | The Application provides a configuration file. |

6.5 Draft User Manual

When the user is happy with his AXCP Rule and validated it with a quick and/or full trial, the final option is to activate the AXCP Rule in the AXCP Rule Engine. In the current version of the prototype the user has to install manually the AXCP Rules in the Scheduler by selecting “Add rule” in Program menu. The command opens a load Dialog for single or multiple selection of AXCP Rules. To start the scheduler, the Start Scheduler command in the “Program” menu has to be called, successively the “Start Grid Functions” allows starting the P2P interface. The scheduler is ready to discover possible AXCP Rule executor in the network. The discovered executors will be displayed in the Executor List area. The scheduler will process information of rules and at the specified times will distribute rules to a rule executor. During the running of the rule, the user can also stop it from the Scheduler by selecting “Kill Rule” in the Command menu or other commands to control the execution of rule. The logs is accessible in real time by calling the “Logs” command in the “View” menu. By pressing the F5 key the logs window is refreshed.

6.6 Examples of usage

The following snapshot shows the main window at runtime:
In the following an example of logs dialog is shown:

### 6.7 Integration and compilation issues

It is a stand alone window application.

### 6.8 Errors reported and that may occur

Not available at this step.
6.9 Rule Executor (AXCP GRID Node)

The rule executor is an application running on a remote computer. It is a computational unit in the distributed rule engines environment. It is based on Javascript engine and executes JavaScript code. To this end it hosts the SpiderMonkey Javascript Ending realised by Mozilla. The main architecture of the Rule Executor is depicted in the following picture:

The main components are:
- **Grid Peer Interface** – the communication support with the AXCP rule scheduler
- **Rule Executor Manager** – the command interface of the engine
- **Script Executor** – It hosts the SpiderMonkey Javascript Engine (called JS Engine)

### 6.9.1 Executor Manager

The Rule Executor Manager is the main program and the interface between the script executor and the scheduler. It hosts the Grid Peer Interface for the communication in the distribute environment based on the technology of the Grid Peer on the scheduler side. The interface allows:

1. receiving commands, messages, requests and files from the Scheduler
2. sending messages, notifications and files to the Scheduler
3. being discovered by the Scheduler during the discovering phase.

The main activity is to:
- generate the profile of the executor to send to the Scheduler
- receive the rule file from the Scheduler
- load the rule in the executor
• manage the launch of the rule execution by means the Launcher
• provide to the Script Executor the support of communication with the Scheduler.
• notify errors, status and the end of execution to the Scheduler.

To realize that, the Rule Executor Manager provides functionalities for:
• Routing messages produced by internal components to the scheduler
• Receiving control messages and commands from the Scheduler
• Parsing and executing commands coming from the scheduler such as:
  o Launch the execution of rule
  o Kill the execution of rule
  o Pause the execution of rule
  o Resume the execution of rule
  o Request profile
  o Request status
• File Transferring to:
  o send the profile of the Rule Executor
  o receive the rule to be executed
• Sending messages and notification to the Scheduler
• Creating the profile of the executor according to the XML schema
• Managing the status of the Executor

Status of the Rule Executor
The Rule Executor status describes the activity of the rule engine. If it is available for running a rule the status value will be “READY”, otherwise if it is working with a rule the value will be “RUNNING”. In event of errors that could break the execution, if they could be managed by software, the executor notifies them to the Scheduler stopping definitively the current execution and resetting the status to the “Ready” value.

6.9.2 Launcher
The role of the Launcher is to start the execution of the script. The main steps that the Launcher has to perform, are:
• Loading the rule XML file received by the Scheduler
• Extracting the script included in the Rule (all the information included in the Definition section of the XML file)
• Initialising the JSEngine environment and preparing the script
• Calling the Script Executor for executing the script

Script Initialization – Before running the script, the Launcher checks and prepares the script code for the execution on JS Engine. In this phase, the JSEngine and the JavaScript script code are prepared according to the SpiderMonkey JS Engine guideline. All the functions related to AXMEDIS plug-ins and arguments of rule are created and initialised. The arguments initialisation allows defining global variables associated with the arguments used in the script by actualising them with values specified in XML rule description. In event of possible errors during the script initialization, a failure message is generated and sent to Executor Manager that routes it to the Scheduler.

6.9.3 Script Manager
The Script Manager is in charge to build the javascript code by assembling all embedded and referenced scripts provided by the AXCP Rule. In the debugging mode, the manager prepares breakpoints to be associated with traps. Each single script provides the list of own breakpoints and the manager uses to generate the full list of absolute references to the merged script. At the same time it associates new references with scripts and the relative line in each single source code. This allows at runtime a fast retrieval of the script and the line where the execution was brought and then use this information in the GUI to show the line of the source code. The script manager is also used to update breakpoints added or removed by the user for instance using the AXMEDIS Rule Editor.
6.9.4 JSENGINE (SpiderMonkey by Mozilla)

The AXMEDIS Rule Executor is equipped with a JavaScript Engine based on SpiderMonkey, the Mozilla's C implementation of JavaScript ([1]). The JS engine supports JS 1.0 through JS 1.5, JS 1.4., JS 1.3 and greater conform to the ECMAScript-262 specification. At its simplest, the JS engine parses, compiles, and executes scripts containing JS statements and functions. The engine handles memory allocation for the JS data types and objects needed to execute scripts, and it cleans up—garbage collects—the data types and objects in memory that it no longer needs. Generally, the JS engine is built as a shared resource. For example, the engine is a DLL on Windows and Windows NT, and a shared library on Unix. The JS engine's API provides functions that fall into the following broad categories:

- Data Type Manipulation
- Run Time Control
- Class and Object Creation and Maintenance
- Function and Script Execution
- String Handling
- Error Handling
- Security Control
- Debugging Support

Conceptually, the JS engine is a shared resource on the system. By embedding engine API calls in the application, requests can be passed to the JS engine for processing. The engine, in turn, processes requests, and returns values or status information back to the application. The following picture illustrates this general relationship:

In truth, the actual relationship between the application and the JS engine is somewhat more complex than shown in Figure 1.1. For example, it assumes that you have already built the JS engine for your platform. It assumes that your application code includes jsapi.h, and it assumes that the first call your application makes to the engine initialises the JS run time.

When the JS engine receives an initialisation request, it allocates memory for the JS run time. The picture reported below illustrates this process:

The run time is the space in which the variables, objects, and contexts used by the application are maintained. A context is the script execution state for a thread used by the JS engine. Each simultaneously existent script or thread must have its own context. A single JS run time may contain many contexts, objects, and variables.

Almost all JS engine calls require a context argument, so one of the first things the application must do after creating the run time is call JS_NewContext at least once to create a context. The actual number of contexts the application needs depends on the number of scripts expected to use at the same time in the
application. One context is needed for each simultaneously existing script in the application. On the other hand, if only one script at a time is compiled and executed by application, then you need only create a single context that you can then reuse for each script. After contexts creation, the built-in JS objects in the engine must be initialized by calling **JS_InitStandardClasses**. The built-in objects include the **Array**, **Boolean**, **Date**, **Math**, **Number**, and **String** objects used in most scripts.

Most applications will also use custom JS objects. These objects are specific to the needs of applications. They usually represent data structures and methods used to automate parts of your application. To create a custom object, you populate a JS class for the object, call **JS_InitClass** to set up the class in the run time, and then call **JS_NewObject** to create an instance of your custom object in the engine. Finally, if your object has properties, you may need to set the default values for them by calling **JS_SetProperty** for each property. Even though you pass a specific context to the JS engine when you create an object, an object then exists in the run time independent of the context. Any script can be associated with any context to access any object. The following figure illustrates the relationship of scripts to the run time, contexts, and objects.

As the previous figure also illustrates, scripts and contexts exist completely independent from one another even though they can access the same objects. Within a given run time, an application can always use any use any unassigned context to access any object. There may be times when you want to ensure that certain contexts and objects are reserved for exclusive use. In these cases, create separate run times for your application: one for shared contexts and objects, and one (or more, depending on your application's needs) for private contexts and objects. **NOTE:** Only one thread at a time should be given access to a specific context.

### 6.9.5 Script Executor

The Script Executor receives the script code and arguments (Selections and parameters), then, it performs the necessary operations for:

- Invoking and initialising the JS Engine and variables.
- Sending the script to the JS Engine.
- Running and managing the communication with the JS Engine **according to the capabilities and functionalities provided by the JS Engine**.
- Routing errors coming from the JS Engine to the Rule Executor Manager.
- Sending Messages coming from the script in execution to the Rule Executor Manager.
The Script Executor will be developed to be used also in the AXCP Rule Editor. As depicted in the software architecture, the editor will be equipped with a Rule Executor. When used inside the AXCP Rule Editor it will be able to work also in two different modes: the rule debugging mode and rule check mode. This will be useful during the definition of a rule since the user will be able to test the rule and to solve possible errors.

**Script Executor: Debugging Mode**
The debugging mode was realised by using the debug function provided by JSDebug API of SpiderMonkey and to be controlled by the AXCP Rule Editor. The Spidermokey APIs permit to:
- put traps in the code corresponding to breakpoints (interrupting the execution)
- defining callbacks for:
  - intercepting the execution of javascript bytecodes
  - intercepting the call of scripted functions
  - intercepting the allocation of new objects
  - intercepting the deallocation of objects and the internal Garbace Collector
- watch variables
- manage the stack of functions
- realise the interface for debug functions and controls for the AXCP Rule Editor.

**Script Executor: Check Mode**
This modality is mainly used by AXCP Rule Editor when it is necessary to check the feasibility of a rule. In the testing mode, the rule is executed in order to:
- verify the correctness of the rule before to send it to the AXCP Rule Engine
- estimate some parameters related to the complexity of the rule. Such parameters will be identified and defined during the project life. They will be used to define a complete profile of the rule in terms of required computational resources.

### 6.9.6 Executor Profile and XML formalisation

The executor profile is the set of metadata that allows to describe the executor in terms of:
1. Computational capabilities
2. Functionalities that the executor provides such as:
   - AXMEDIS Plug-In installed.
   - External tools Plug-In installed

The following table describes each metadata of profile:

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Computer Name</td>
<td>Name of the computer hosting the rule executor</td>
</tr>
<tr>
<td>URL</td>
<td>IP address</td>
</tr>
<tr>
<td>AXTID</td>
<td>The ID of a specific instance related to the AXTID</td>
</tr>
<tr>
<td>AXRTID</td>
<td>The AXMEDIS Registered Tool Id associated with the Rule Executor application</td>
</tr>
<tr>
<td>SO</td>
<td>The Operating System</td>
</tr>
<tr>
<td>Version</td>
<td>The SO version</td>
</tr>
<tr>
<td>CPU</td>
<td>The type of CPU</td>
</tr>
<tr>
<td>Clock</td>
<td>The clock of CPU</td>
</tr>
<tr>
<td>RAM size</td>
<td>The amount of memory</td>
</tr>
<tr>
<td>HD-space</td>
<td>The amount of disk space available</td>
</tr>
<tr>
<td>Location</td>
<td>Where the computer is located</td>
</tr>
<tr>
<td>Workload</td>
<td>The percentage of availability during the time period</td>
</tr>
<tr>
<td>Transfer rate from AXDB</td>
<td>The network capability for transferring a file from the AXMEDIS Database to the rule executor machine.</td>
</tr>
<tr>
<td>Plug-In</td>
<td>It provides the name and the version. Since the executor can host many plug-in, this is field represents a list of Plug-In</td>
</tr>
</tbody>
</table>
The definition of profile for a rule executor peer was formalised by means the XML Schema as reported in this section. The profile describes the capability of the machine where the rule executor peer is running in terms of hardware, software and axmedis plugin configuration.

**Profile element**

```xml
<xs:element name="Profile">
  <xs:complexType>
    <xs:sequence>
      <xs:element name="Computer_Name" type="xs:string"/>
      <xs:element name="IP_Address" type="xs:anyURI"/>
      <xs:element name="CPU" type="xs:string"/>
      <xs:element name="Clock" type="xs:float"/>
      <xs:element name="Location" type="xs:string"/>
      <xs:element name="AXTID" type="xs:string"/>
      <xs:element name="AXRTID" type="xs:string"/>
      <xs:element name="OS" type="xs:string"/>
      <xs:element name="OS_Version" type="xs:string"/>
      <xs:element name="RAM_Size" type="xs:string"/>
      <xs:element name="HD_Space" type="xs:string"/>
      <xs:element name="Transf_Rate" type="xs:unsignedInt"/>
      <xs:element name="WorkLoad">
        <xs:complexType>
          <xs:sequence>
            <xs:element name="Percentage" type="xs:float"/>
            <xs:element name="Start_Time" type="xs:time"/>
            <xs:element name="End_Time" type="xs:time"/>
          </xs:sequence>
        </xs:complexType>
      </xs:element>
      <xs:element name="Plug_In" maxOccurs="unbounded">
        <xs:complexType>
        </xs:complexType>
      </xs:element>
    </xs:sequence>
  </xs:complexType>
</xs:element>
```

The diagram shows the elements and their relationships as follows:

- **Computer_Name**
- **IP_Address**
- **CPU**
- **Clock**
- **Location**
- **AXTID**
- **AXRTID**
- **OS**
- **OS_Version**
- **RAM_Size**
- **HD_Space**
- **Transf_Rate**
- **WorkLoad**
- **Plug_In**

The diagram illustrates the hierarchical structure of the profile elements.

6.10 Configuration Parameters

In this section the set of parameters regarding the configuration of the editor are listed. Such parameters are grouped into modules as reported below:

### 6.10.1 AXMEDIS Rule Executor

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>XML_RULE_PATH</td>
<td>it is the directory where the rule will be saved</td>
</tr>
<tr>
<td>XML_XSD_PATH</td>
<td>It is the directory where xml schema (XSD files) are stored</td>
</tr>
<tr>
<td>LOGS_PATH</td>
<td>It is the directory where logs are stored</td>
</tr>
</tbody>
</table>

### 6.10.2 AXMEDIS_GRID_SUPPORT_SETTINGS

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERV_PORT</td>
<td>It is the value of the port used by the Grid Interface</td>
</tr>
<tr>
<td>SERV_PORT2</td>
<td>It is the value of the port used by the Grid Interface</td>
</tr>
<tr>
<td>SERV_PORT3</td>
<td>It is the value of the port used by the Grid Interface</td>
</tr>
</tbody>
</table>
### 6.10.3 AXMEDIS Plugin Manager

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLUGINS_PATH</td>
<td>It is the directory where the DLL of plug-ins with their profiles (workflow, adaptation, descriptor and fingerprint estimators) are stored.</td>
</tr>
</tbody>
</table>

### 6.10.4 AXMEDIS Database

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>The user name for logging into Database</td>
</tr>
<tr>
<td>passwd</td>
<td>The passoword for logging into Database</td>
</tr>
<tr>
<td>LoaderWSEndPoint</td>
<td>It is the URL for…</td>
</tr>
<tr>
<td>HTTPPath</td>
<td></td>
</tr>
<tr>
<td>UploadPath</td>
<td></td>
</tr>
<tr>
<td>SaverWSEndPoint</td>
<td></td>
</tr>
</tbody>
</table>

### 6.10.5 AXMEDIS Selection

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Possible values</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAIN_QUERY_SUPPORT_WSDL</td>
<td>It is the URL of the WSDL for using the Main Query Support</td>
</tr>
<tr>
<td>SELECTION_ARCHIVE_WSDL</td>
<td>It is the URL of the WSDL for using the Selection Archive</td>
</tr>
</tbody>
</table>

Example of Configuration file:

```xml
<?xml version="1.0" encoding="UTF-8" standalone="no" ?>
<Configuration xmlns="http://www.axmedis.org/configuration">

   <Module category="" id="AXMEDIS_RULE_EXECUTOR">

6.10.6 Rule Executor Class Diagrams

The following class diagram shows main components of the Rule Executor. The diagram provides a view of executor core system:

- **JSEngine** – It is the SpiderMonkey JavaScript Engine. It is the set of APIs provided by the Library
- **AxJSEngine** – It is the component that models the Script Executor
- **AxExecutorManager** – It is the component that models the Executor Manager and Launcher
- **AxJSScriptManager** – It is the component that models the Script Manager
- **AxJSEngineOutput** – It is the component that models the Engine Output
- **AxJSDataType** – It is the component that collects all JS Data Type derived from the AXMEDIS Framework and extends the built in classes provided by the JSEngine

AxJSEngine Output System: A) output for GRID; B) output for Stand Alone
6.11 User interface description

The User Interface of the rule executor as GRID Node is shown in the following picture. It is a console application and the output of the engine for direct messages.

6.12 Technical and Installation information

| References to other major components needed | The AXCP Grid Node works in conjunction with the AXCP Rule Scheduler. |
| Problems not solved                        | The current version is not equipped with a system to limit the request of CPU. So it could happen that the run of a rule requires 100% of CPU. This will be solved in the next version. |
| Configuration and execution context        | The Application provides a configuration file. |

The AXCP Rule Executor is provided as two executable files:
- Stand alone AXCP Executor as console application for running AXCP Rule
- AXCP Grid Node Executor as console application for the GRID Environment

Before the first launch of the application, the user should setup the configuration file in order to provide the right value to the constants and parameters used by the application. See the section of the Configuration Parameters

6.14 Examples of usage

**Stand alone AXCP Executor**
To run the Executor with an AXCP Rule, the user has to open the CMD dialog of Windows and type the line command using the option 0 as following:
```
axruleexecutor.exe <rule path> -0
```

**AXCP Grid Node Executor**
To launch the AXCP Grid Node, the user has to double click on axcpgridnone.exe executable file

6.15 Integration and compilation issues

The Visual Studio solution provides to project for executable files.

### 7.1 General Description of the Module

The Content Format Engine provides formatting functionalities that are used by the AXCP GRID and by format tools (*Template Editor and Selector*, *Style Editor and Selector*, *Style Optimizer*) integrated within the AXMEDIS SMIL Editor. The goal of the Content Format Engine is integrating digital resources, contained within an AXMEDIS Object, in a multimedia presentation (based on the SMIL language) suitable for the final user. The Engine is based on templates and style-sheets that define respectively the basic structure and the look-and-feel of the presentation. To get best results in terms of adaptation to customer’s needs, the Content Format Engine performs its choices according to profiles that describe personal preferences, user’s device capabilities and delivery context.

The Content Format Engine Module is composed of five main subsystems:
Resources and profiles (user, device and context profiles) represent the input to the Format Engine; templates and styles are its output; the format management implements the filtering and optimization logic. The format management subsystem is logically divided into three blocks:

- **association** block receives as input the digital resources, profiles, and some additional information that provides basic knowledge about the type of the presentation, its output format and the target platform. It performs a mapping of resources, profiles and other compositional properties, and chooses most suitable templates, according to a set of weights. The output of this block is the indication of a template, which describes the basic structure of the presentation;

- **styling and optimization** blocks select a style-sheet for the given template and adjusts their parameters to cope with the profiles, managing the adaptation and the transcoding of the involved media. They perform a mapping of resources, profiles and other compositional properties, and choose most suitable style-sheets and optimization values, according to a set of weights. The output of this block is the final format description.

The optimization process is a very critical and complex phase, that may involve many aspects. Media encoding is part of the optimization: to fit the optimized layout, media may necessitate transcoding, resampling or moreover, media have to be transformed (scaled, rotated, etc.) to fit the adapted layout.

The choice of the optimization algorithm is very important: the problem of finding the best combination of a potentially large number of layout parameters is NP-complete, therefore the computational time to determine an exact solution is not reasonable. A more practical approach is to
search “good” solutions, with methods such as Genetic Algorithms that can be distributed on the AXMEDIS GRID.

The system is supposed to work in two modalities:

- **an interactive modality**, which allows the author to choose or create templates and style-sheets and control the results of the adaptation. This modality also relies on the AXMEDIS SMIL Editor and Player;
- **an automatic modality**, that manages the whole process following a set of rules; these rules use the JavaScript modules that wrap the Format Engine.

In either the interactive or the automatic modality, the *format_manager* is used to set profiles and resources, that are the input of the Format Engine. The input is used by the Association block to associate the document with an existing template. The Association block can also interact with the user: the system either requires a choice between different options (if several templates match the input) or allows the creation of a new template.

To correctly associate the input set with a suitable template, the multimedia resources should be ordered or logically grouped, according to their semantic or spatial relationships, using the hierarchical organization of the AXMEDIS Object. Such relationships may also reflect the logic within the querying process.

After that, the style-sheet selection is performed by the Styling/Optimization block: in the automatic modality one of the style-sheets created for the given template is selected following profiles indications; otherwise, a filtered list of style-sheets is proposed to the author, who can choose one of them or create a new one. The final stage is the optimization: the parameters of the style-sheet are optimized following the profiles specification, and all media are transcoded and transformed to fit the final layout.

### 7.1.1 Resources management

Resources that have to be formatted may come from various sources:

- resources or references included into an AXMEDIS object;
- list of resources accessible in the local file system or through an URI;
- references resulting from a query;
- references returned from an external library.

Anyway, resources may be represented by an XML descriptor. Descriptors are not stored, but only created in memory during the formatting process.

The *resource_descriptor* specifies:

- **id**: identifier;
- **location**: the resource address (URI, file system location, AXMEDIS Object ID (AXOID), etc.).
  
  Regarding the AXObjects, we consider that each single resource is encapsulated into a single AXObject and thus identified through its AXOID; by the way, the single-resource AXObject may be encapsulated into a composite AXObject;
- **type**: the MIME top-level type of the resource (i.e.: image, audio, text, video, or application);
- **meta** (optional): additional information related to the resource;
- **parent** (optional): the reference of the parent resource. Typically, it will be used for navigate into a hierarchy of encapsulated AXObjects;
- **related-to** (optional): the reference of another resource which has strong logical relationship with the current resource;
- **subtype**: the MIME subtype (e.g.: bmp, jpg, wav, mp3, rtf, txt, etc.).
properties: depending on the type, specifies available attributes (size, resolution, codec, encoding, etc.);

category (optional): the way we intend to use the resource. For instance: a text may be used as document title, as page body, as figure caption, as button label; an image may be used as page header, as background, as figure; and so on.

For defining resource categories, we consider a typical web-based content page that holds a set of content comprising: title, sub-title (if needed), body text (resizable and scrollable in respect to display area), some multimedia content (with related controls when needed), a quick navigation bar (if needed to allow content browsing) and potentially comprising or associated with a control bar (to allow overall content management: print, save…) and a footer usually holding copyright information. The usual structures are represented in the following picture.

The XML Schema for the resource descriptor is depicted below.
7.1.2 Templates management

Each template has an associated descriptor, that resumes its principal characteristics. Descriptors are stored locally and refer to templates that may be stored elsewhere. A template descriptor contains some information that comes from a template analysis, and other inputs from the template author.

With a template analysis we can get:

- type of the resources needed by the template, and their number;
- hierarchical (tree-shaped) organization of the resources within the template;
- category indications provided by the author for each resource (optional).

The indications that the template author has to supply are:

- ID;
- general category for the template, chosen from a predefined list (e.g.: slide show, video clip, interactive music, interactive video, hypertext, audio/video karaoke, electronic book, kiosk, training tutorial, etc.);
- output format (e.g.: SMIL, MPEG4, HTML, etc.). Some templates could include elements and/or structures that may not be rendered in all formats; for instance, SMIL and MPEG4 are not fully interchangeable, and HTML is really poor if compared to SMIL.
- target devices (e.g.: PC, mobile, kiosk, PDA, etc.);
- metadata, with a general template description.

The XML Schema for the template descriptor is depicted below.

7.1.3 Templates filtering
The \textit{template filter} performs various types of ranking for the templates in the \textit{templates list}. Each element of these filtered lists is a reference to an element of the complete \textit{templates list}; moreover, each filtered list may be used as source for a new filtering operation.

Filtering operations are based on criteria such as:

- general category, target devices and output format for the template, compared with author inputs;
- correspondence between type and number of resources needed by the templates and the \textit{resources list};
- correspondence between hierarchical organizations of template and resources;
- correspondence between category attributes for resources and template.

The relevance of the criteria is determined by weights, selected from a list of possibilities (managed by a \textit{format criteria} and stored in a \textit{Weights} table): the author may choose the preferred set of weights or define a new one.

Once we have evaluated the criteria we have to normalize their values \((C_1, \ldots, C_n)\) between 0 and 1; then we can get the normalized score of a template:

\[
\text{score}(T) = \frac{W_1 C_1 + W_2 C_2 + \ldots + W_n C_n}{W_1 + W_2 + \ldots + W_n}
\]

### 7.1.4 Style-sheets management

Each style-sheet has an associated descriptor, that resumes its principal characteristics. A \textit{style descriptor} contains some information that comes from a style-sheet analysis, and other inputs from the style-sheet author.

With a style-sheet analysis we can get:

- parameters specified for the optimization.

The indications that the template author has to supply are:

- ID;
- ID of the related template;
- target devices (optional), that may be a subset of devices specified in the template;
- metadata (optional), with a general style-sheet description.

The XML Schema for the style-sheet descriptor is depicted below.
7.1.5 Style-sheets filtering
The *style_filter* performs various types of ranking for the style-sheets in the *styles_list*. Each element of these filtered lists is a reference to an element of the complete *styles_list*; moreover, each filtered list may be used as source for a new filtering operation. Furthermore, this class uses the *optimizer* to get optimized values for parameters defined in the style-sheets. Filtering operations are based on:

- related template;
- target devices;
- need for optimization (presence of parameters).

The relevance of the criteria is determined by weights, selected from a list of possibilities (managed by a *format_criteria* and stored in a *Weights* table): the author may choose the preferred set of weights or define a new one. Once we have evaluated the criteria we have to normalize their values (C1, ..., Cn) between 0 and 1; then we can get the normalized score of a template:

\[
\text{score}(T) = \frac{(W1 \times C1 + W2 \times C2 + ... + Wn \times Cn)}{(W1 + W2 + ... + Wn)}
\]

7.1.6 Style-sheet optimization
The *optimizer* class manages the document optimization. This task is done assigning values to the parameters specified in the style-sheets: a choice of values that follow the profiles, allows a customization of the layout and of the general look-and-feel of the document. Such an optimization is an hard problem that may involve many parameters; the search space is large and it is unlikely to find an optimal solution, thus metaheuristic algorithms can get good results.

Genetic Algorithms (GA) are adaptive metaheuristic search algorithm premised on the evolutionary ideas of natural selection and genetic. Possible solutions are considered as a population of individuals that undergo selection in the presence of variation-inducing operators such as mutation and recombination (crossover). Initially many individual solutions are randomly generated to form an initial population. At each successive step, a part of the existing population is selected to breed a new generation: solutions are evaluated by a fitness function and stochastic methods, that select best individuals. This generational process is repeated until a termination condition (minimum criteria, number of generations, computational time, etc.) has been reached. Typically, parameters defined in the style-sheets will be position and dimensions of the regions composing the layout. The search of best layout can be modeled as a 2D bin-packing problem of rectangular shapes on a rectangular canvas and solved using the GA approach. Other parameters could be: screen dimensions, text properties (font size, alignment, etc.), timing, colors, etc. The fitness function of GA should consider several aspects: regions overlapping, alignment and maximization, minimization of the unused space, text readability, etc. The relevance of each aspect is evaluated according to a set of weights (managed by a *format_criteria* and stored in a *Weights* table).

7.1.7 Criteria
The *format_criteria* class manages weights used for template filtering, style-sheet filtering and optimization. Each set of weights is stored together with an unique id, a description (metadata), and its type (template, style or optimizer).

7.1.8 Profiling
The Content Format Engine needs information about the destination of the document that has to be formatted, to perform best choices during selection and optimization. Such information should be grouped in three profiles:

1. user profile;
2. device profile;
3.  context (network) profile.

Profiles may be static or dynamic and may depend on the category of the client device (mainly PC or mobile):

- information about users is collected statically and does not depend on the device category;
- information about device is collected both statically and dynamically and depends on the device category;
- information about context is collected dynamically and does not depend on the device category.

The AXMEDIS Device profile and Context profile are subsets of MPEG-21 DIA while User profile contains some elements of MPEG-21 DIA and some additional AXMEDIS elements in it.

MPEG-21 Digital Item Adaptation specifies the syntax and semantics of tools that may be used to assist the adaptation of Digital Items; these tools are clustered into eight major categories. We are specially interested in the Usage Environment Description (UED) Tools, which include User characteristics, terminal capabilities, network characteristics and natural environment characteristics. These tools provide descriptive information about the various properties of the usage environment, which originate from Users, to accommodate, for example, the adaptation of Digital Items for transmission, storage and consumption.

The Schema used for descriptions in MPEG-21 DIA defines:

1.  the root elements;
2.  the base types that form the hierarchy of the description.

The functionality of a root element is to describe the initial wrapper or root element of descriptions. Two root elements are defined:

1.  a DIA root element, which is used for complete descriptions:

   
   ![Diagram](image-url)

   The DescriptionMetadata element can be used to contain the metadata for the descriptions contained within the DIA description.

   Description and Reference are elements (or references to elements) whose type is derived from DIADescriptionType.

2.  a DIADescriptionUnit root element, which is used to represent partial information from a complete description:
Two base types are defined:

1. a DIA\textit{BaseType}, that provides the base abstract type of the type hierarchy:

2. a DIA\textit{DescriptionType}, that extends DIA\textit{BaseType} and provides the base abstract type for a subset of types that may follow the DIA root element:

7.1.9 User profile

User characteristics are described in terms of:

- general information (e.g.: name, contact info, etc.);
- usage preferences and history;
- presentation preferences (audio, e.g.: equalizer settings, frequency, volume, etc.; display, e.g.: color temperature settings, contrast, brightness, etc.);
- accessibility (auditory and visual impairments);
- location.

Using DIA types and subtypes, the information mainly required by the Content Format Engine is:

- \textit{UserInfo}: specifies general information about users, such as name and contact information;
- \textit{AudioPresentationPreferences}: specifies the preferences of a user regarding the presentation or rendering of audio resources (such as the preferred volume, frequency equalizer settings, and audible frequency);
- \textit{DisplayPresentationPreferences}: specifies the preferences of a user regarding the presentation or rendering of images and videos;
- \textit{ColorPreference}: describes preferences related to color attributes;
- \textit{GraphicsPresentationPreferences}: specifies presentation preferences related to graphics media;
- \textit{ConversionPreference}: enables users to specify preferences to guide the conversion of resources when a terminal or network cannot support the consumption or transport of a particular modality or format;
• PresentationPriorityPreference: lets the user have choices on the presentation qualities of different resources at the output of the content adaptation process.

An example of user profile is the following:

```xml
<DIA>
  <Description xsi:type="UsageEnvironmentType">
    <UsageEnvironmentProperty xsi:type="UsersType">
      <User>
        <UserCharacteristic xsi:type="UserInfoType">
          <UserInfo xsi:type="mpeg7:PersonType">
            <mpeg7:Name>
              <mpeg7:GivenName>John</mpeg7:GivenName>
              <mpeg7:FamilyName>Doe</mpeg7:FamilyName>
            </mpeg7:Name>
          </UserInfo>
          <UserCharacteristic xsi:type="AudioPresentationPreferencesType">
            <VolumeControl>0.85</VolumeControl>
            <FrequencyEqualizer>
              -10 -10 -10 -10 -10 -10 -10 -10 -10 -10
              -10 -10  0   0   0 10 10 10
              -10 -10 -10 -10 -10 -10 -10 -10 -10 -10
            </FrequencyEqualizer>
            <AudibleFrequencyRange>
              <StartFrequency>20</StartFrequency>
              <EndFrequency>20000</EndFrequency>
            </AudibleFrequencyRange>
            <Soundfield>
              <ImpulseResponse href="http://www.sac.or.kr/concertHall/hallImp.wav">
                <SamplingFrequency>44100</SamplingFrequency>
                <BitsPerSample>16</BitsPerSample>
                <NumOfChannels>1</NumOfChannels>
              </ImpulseResponse>
            </Soundfield>
            <SoniferousSpeed>0.5</SoniferousSpeed>
          </UserCharacteristic>
        </User>
      </UsageEnvironmentProperty>
    </Description>
  </UsageEnvironmentProperty>
</DIA>
```

7.1.10 Device profile

Terminal characteristics are described in terms of:

- codec capabilities (encoding and decoding formats);
- device properties (user interaction support, e.g.: mouse, pen or other types of input devices; device class, e.g.: PC, PDA, Set-top box, etc.);
- input-output characteristics (display and audio output capabilities, e.g.: resolution, rendering format, bits/pixel, color capable, frequency ranges, output power, SNR, etc.).

Using DIA types and subtypes, the information mainly required by the Content Format Engine is:

- **Terminal**: specifies the capabilities and properties of a single terminal, that include coding and decoding capabilities, device properties and input-output capabilities;
- **CodecCapabilities**: specifies the format that a particular terminal is capable of encoding or decoding;
- **Display**: specifies the capabilities and properties of a single display;
- **AudioOutput**: specifies the capabilities and properties of a single audio output;
- **UserInteractionInput**: specifies the various types of User interaction input support that is available on a particular device;
- **DeviceClass**: makes possible to identify consumer devices such as PC and mobile phones from communication devices such as gateways and routers;
• **Storage**: specifies storage characteristics of the terminal, which does include input and output transfer rates, the size of the storage and whether the storage is writeable or not.

An example of device profile is the following:

```xml
<DIA>
  <Description xsi:type="UsageEnvironmentType">
    <UsageEnvironmentProperty xsi:type="TerminalsType">
      <Terminal>
        <TerminalCapability xsi:type="StoragesType">
          <Storage xsi:type="StorageType">
            <StorageCharacteristic xsi:type="StorageCharacteristicsType">
              inputTransferRate="8" size="1200" writable="true"/>
          </Storage>
        </TerminalCapability>
        <TerminalCapability xsi:type="DeviceClassType">
          <DeviceClass href="urn:mpeg:mpeg21:2003:01-DIA-DeviceClassCS-NS:1">PC</DeviceClass>
        </TerminalCapability>
        <TerminalCapability xsi:type="DisplaysType">
          <Display id="primary_display">
            <DisplayCapability xsi:type="DisplayCapabilityType">
              <Mode>
                <Resolution horizontal="720" vertical="480"/>
              </Mode>
            </DisplayCapability>
          </Display>
          <Display id="secondary_display">
            <DisplayCapability xsi:type="DisplayCapabilityType">
              <Mode>
                <Resolution horizontal="176" vertical="144"/>
              </Mode>
            </DisplayCapability>
          </Display>
        </TerminalCapability>
        <TerminalCapability xsi:type="UserInteractionInputsType">
          <UserInteractionInput>
            <UserInteractionInputSupport xsi:type="MicrophoneType"/>
          </UserInteractionInput>
          <UserInteractionInput>
            <UserInteractionInputSupport xsi:type="KeyInputType">
              <KeyInput href="urn:mpeg:mpeg21:2003:01-DIA-KeyInputCS-NS:1">PCKeyboard</KeyInput>

          <Decoding xsi:type="VideoCapabilitiesType">
            <Format href="urn:mpeg:mpeg7:cs:VisualCodingFormatCS:2001:3.1.2">AMR</Format>
          </Decoding>
        </TerminalCapability>
      </Terminal>
    </UsageEnvironmentProperty>
  </Description>
</DIA>
```
7.1.11 Context profile

Context (network and natural environment) characteristics are described in terms of:

- capabilities (e.g.: capacity of the channel, minimum guaranteed bandwidth, etc.);
- conditions (e.g.: error rate, delay, available bandwidth, etc.);
- location and time;
- audio-visual (e.g.: audio noise levels, illumination conditions affecting a display, etc.).

Using DIA types and subtypes, the information mainly required by the Content Format Engine is:

- Network: describes a single network in terms of its static capabilities and time-varying conditions;
- NaturalEnvironment: describes a single natural environment in terms of the location and time of usage of a Digital Item, as well as audio-visual characteristics of the natural usage environment;
- Location: describes the location of the usage of a Digital Item;
- Time: describes the time of the usage of a Digital Item.

An example of context profile is the following:

```xml
<DIA>
  <Description xsi:type="UsageEnvironmentType">
    <UsageEnvironmentProperty xsi:type="NetworksType">
      <Network>
        <NetworkCharacteristic xsi:type="NetworkCapabilityType">
          maxCapacity="384000" minGuaranteed="32000"/>
        <NetworkCharacteristic xsi:type="NetworkConditionType" duration="PT330N1000F">
          <AvailableBandwidth maximum="256000" average="80000"/>
          <Delay packetTwoWay="330" delayVariation="66"/>
          <Error packetLossRate="0.05"/>
        </NetworkCharacteristic>
      </Network>
    </UsageEnvironmentProperty>
    <UsageEnvironmentProperty xsi:type="NaturalEnvironmentsType">
      <NaturalEnvironment>
        <NaturalEnvironmentCharacteristic xsi:type="LocationType">
          <Location>
            <mpeg7:GeographicPosition>
              <mpeg7:Point longitude="135.75" latitude="35.00" altitude="10.00"/>
            </mpeg7:GeographicPosition>
          </Location>
        </NaturalEnvironmentCharacteristic>
      </NaturalEnvironment>
    </UsageEnvironmentProperty>
  </Description>
</DIA>
```
7.2 Module Design in terms of Classes

The class diagram for the Content Format Engine is depicted in the following figure:

The diagram is divided in five areas:

1. Resources management (resource_descriptor and resources_list classes);
2. Templates management (template_descriptor and templates_list classes);
3. Style-sheets management (style_descriptor and styles_list classes);
4. Profiles management (device_info, user_info and context_info classes, that specializes the profile_info);
5. Format management (format_filter - that generalizes style_filter, template_filter and optimizer - and format_criteria classes).

7.2.1 Format manager

The format_manager drives the whole process: this class receives reference to profiles (device, user and context) and resources; offers methods to browse and search templates and style-sheets, and to optimize them.

format_manager

| +addResource(in uri : string) : bool |
The format_filter class generalizes template_filter, style_filter and optimizer classes.

format_filter

```
+setCriteria(in id : string) : bool
sets criteria used for filtering
```

```
+setCriteria(in id : string) : bool
+filter() : string[]
+filterList(in idList : string[]) : string[]
```

```
+setCriteria(in id : string) : bool
+filter(in templateId : string) : string[]
+filterList(in idList : string[]) : string[]
```

```
+setCriteria(in id : string) : bool
+optimize(in styleId : string) : int[]
```

```
+setCriteria(in id : string) : bool
+optimize(in styleId : string) : int[]
```

7.2.2 Resources management

The resource_descriptor class is used to describe digital resources involved in the formatting process. Descriptors are not stored, but only created in memory during their formatting process. The single-parameter constructor creates a resource_descriptor loading data from an XML file; the other one receives data as input parameters.

resource_descriptor

```
+resource_descriptor(in address : string)
constructor from XML file
```

```
```
The resources_list collects the descriptors of all the resources involved in the current formatting activity. It offers methods to browse and search resources and information about a single resource or aggregated data.

### 7.2.3 Templates management

The template_descriptor class is used to describe templates used in the Format Engine. Descriptors are stored locally, but may refer to templates stored elsewhere.

```plaintext
template_descriptor
+template_descriptor(in id : string)
constructor
+getData() : string
getter method
+getLocation() : string
+setLocation(in address : string) : bool
getter/setter method
+getMetadata() : string
+setMetadata(in meta : string) : bool
getter/setter method
+getDevice() : string
+setDevice(in device : string) : bool
getter/setter method
+getRelated() : string
+setRelated(in relatedId : string) : bool
getter/setter method
+setCategory(in category : string) : bool
setter method
```
`+setDevice(in device : string) : bool
getter/setter method
+getFormat() : string
+setFormat(in outformat : string) : bool
getter/setter method
+getCategory() : string
+setCategory(in category : string) : bool
getter/setter method
+getHierarchy() : string
returns the XML hierarchy of the resources within the template
+getRes() : int
returns the number of resources needed by the template
+getResByType(in type : string) : int
returns the number of resources of the given type needed by the template
+getTypes() : int
getter method

The `templates_list` collects all the template descriptors and offers methods to browse the list and to get individual or aggregate data.

`templates_list`

`+templates_list(in uri : string)
constructor; needs the address of the descriptors directory
+load() : bool
fill the list with existing template descriptors
+add(in id : string, in location : string, in outformat : string, in category : string, in device : string, in meta : string) : bool
creates a new template descriptor
+addTemplate(in id : string, in xml : string, in outformat : string, in category : string, in device : string, in meta : string) : bool
creates and stores a new template and its descriptor
+getData(in id : string) : string
getter method
+getLocation(in id : string) : string
getter method
+getMetadata(in id : string) : string
getter method
+getDevice(in id : string) : string
getter method
+getFormat(in id : string) : string
getter method
+getCategory(in id : string) : string
getter method
+getHierarchy(in id : string) : string
returns the XML hierarchy of the resources within the template
+getRes(in id : string) : int
returns the number of resources needed by the template
+getResByType(in id : string) : int
returns the number of resources of the given type needed by the template
+getType(in id : string) : int
returns the number of different resource types needed by the template

7.2.4 Templates filtering
The `template_filter` class sorts templates contained in `templates_list`, according to `format_criteria`.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>+setCriteria(in id : string) : bool</code></td>
<td>sets criteria used for filtering</td>
</tr>
<tr>
<td><code>+filter() : string[]</code></td>
<td>returns IDs of selected templates</td>
</tr>
<tr>
<td><code>+filterList(in idList : string[]) : string[]</code></td>
<td>filters a list of already filtered templates</td>
</tr>
</tbody>
</table>

### 7.2.5 Style-sheets management

The `style_descriptor` class is used to describe style-sheets used in the Format Engine. Each style-sheet is univocally linked to a template with its ID. Descriptors are stored locally, but may refer to style-sheets stored elsewhere.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>+style_descriptor(in id : string)</code></td>
<td>constructor</td>
</tr>
<tr>
<td><code>+getData() : string</code></td>
<td>getter method</td>
</tr>
<tr>
<td><code>+getLocation() : string</code></td>
<td>getter/setter method</td>
</tr>
<tr>
<td><code>+getLocation(in address : string) : bool</code></td>
<td>getter/setter method</td>
</tr>
<tr>
<td><code>+getMetadata() : string</code></td>
<td>getter/setter method</td>
</tr>
<tr>
<td><code>+setMetadata(in meta : string) : bool</code></td>
<td>getter/setter method</td>
</tr>
<tr>
<td><code>+getDevice() : string</code></td>
<td>getter/setter method</td>
</tr>
<tr>
<td><code>+setDevice(in device : string) : bool</code></td>
<td>getter/setter method</td>
</tr>
<tr>
<td><code>+getTemplate() : string</code></td>
<td>getter/setter method</td>
</tr>
<tr>
<td><code>+setTemplate(in template : string) : bool</code></td>
<td>getter/setter method</td>
</tr>
<tr>
<td><code>+getParamNum() : int</code></td>
<td>returns the number of parameters defined within the style-sheet</td>
</tr>
<tr>
<td><code>+getParams() : string[]</code></td>
<td>returns the list of parameters defined within the style-sheet</td>
</tr>
</tbody>
</table>

The `styles_list` collects all the style-sheet descriptors and offers methods to browse the list and to get individual or aggregated data.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>+styles_list(in uri : string)</code></td>
<td>constructor; needs the address of the descriptors directory</td>
</tr>
<tr>
<td><code>+load() : bool</code></td>
<td>fill the list with existing style-sheet descriptors</td>
</tr>
<tr>
<td><code>+add(in id : string, in location : string, in device : string, in metadata : string, in template : string) : bool</code></td>
<td>creates a new style descriptor</td>
</tr>
<tr>
<td><code>+addStyle(in xml : string, in id : string, in device : string, in metadata : string, in template : string) : bool</code></td>
<td>creates and stores a new style-sheet and its descriptor</td>
</tr>
<tr>
<td><code>+getData(in id : string) : string</code></td>
<td>getter method</td>
</tr>
</tbody>
</table>
7.2.6 Style-sheets filtering

The style_filter class sorts style-sheets contained in styles_list, according a format_criteria.

style_filter

+setCriteria(in id : string) : bool
sets criteria used for filtering
+filter(in templateId : string) : string[]
returns IDs of selected style-sheets for the given template
+filterList(in idList : string[]) : string[]
filters a list of already filtered style-sheets

7.2.7 Style-sheet optimization

The optimizer class determines optimized values for parameters contained in the style-sheet, according to a format_criteria.

optimizer

+setCriteria(in id : string) : bool
sets criteria used for optimization
+optimize(in styleId : string) : int[]
optimize the selected style-sheet

7.2.8 Criteria

The format_criteria class manages weights for templates filtering, style-sheets filtering and optimization.

format_criteria

+addWeights(in id : string, in meta : string, in type : string, in weights : int[]) : bool
stores a new set of weights with its related information
+getWeights(in id : string) : int[]
+setWeights(in id : string, in weights : int[]) : bool
getter/setter method
+getType(in id : string) : string
+setType(in type : string, in id : string) : bool
getter/setter method
+getMetadata(in id : string) : string
+setMetadata(in meta : string, in id : string) : bool
getter/setter method
7.3 Examples of usage

The format_manager is used to manage the whole formatting process that starts with setting the inputs and ends with the SMIL production. The following example describes a possible interaction with a Rule Executor:

```java
format_manager fm();
for (int i = 0; i < resources.size(); i++) {
    // set the resource list
    fm.addResource(resources.item(i));
}
// set profiles
fm.setDevice(myDevice.uri());
fm.setUser(myUser.uri());
fm.setContext(myContext.uri());
// filtering and optimization
String[] tList = fm.filterTemplate();
// Rule Executor chooses its preferred template...
String tId = tList[0];
String[] sList = fm.filterStyle(tId);  // Rule Executor chooses its preferred style-sheet...
String sId = sList[0];
int[] values = optimize(sId);        // producing SMIL
String result = apply(sId, values);
```

The following sequence diagram illustrates the whole interaction and roles played by different objects:

![Sequence Diagram](image)

7.4 Formal description of algorithm

7.4.1 Genetic Algorithm

Genetic Algorithms are inspired by Darwin's theory of evolution and use an evolutionary process to find solutions of a problem.

AXMEDIS Project
Algorithm begins with a set of solutions (represented by “chromosomes”) called “population”. Solutions from one population are taken and used to form a new population, using crossover and mutation mechanisms. This is motivated by a hope, that the new population will be better than the old one. Solutions are selected to form new solutions (“offspring”) according to their fitness: the more suitable they are the more chances they have to reproduce. This is repeated until some condition (e.g.: number of populations, improvement of the best solution, etc.) is satisfied.

GAs evolve according to the following pseudo-code description:

1. [Start] Generate random population of n chromosomes (suitable solutions for the problem)
2. [Fitness] Evaluate the fitness f(x) of each chromosome x in the population
3. [New population] Create a new population by repeating following steps until the new population is complete:
   3.1. [Selection] Select two parent chromosomes from a population according to their fitness (the better fitness, the bigger chance to be selected)
   3.2. [Crossover] With a crossover probability cross over the parents to form new offspring (children). If no crossover was performed, offspring is the exact copy of parents.
   3.3. [Mutation] With a mutation probability mutate new offspring at each locus (position in chromosome).
   3.4. [Accepting] Place new offspring in the new population
4. [Replace] Use new generated population for a further run of the algorithm
5. [Test] If the end condition is satisfied, stop, and return the best solution in current population
6. [Loop] Go to step 2

7.5 Formal description of format

7.5.1 Formal description of resource descriptor
The following XML Schema defines the resource descriptor (resource_descriptor.xsd).

```
<xs:element name="resource">
  <xs:annotation>
    <xs:documentation>Single-resource descriptor</xs:documentation>
  </xs:annotation>
  <xs:complexType>
    <xs:sequence>
      <xs:element name="info">
        <xs:annotation>
          <xs:documentation>Resource information</xs:documentation>
        </xs:annotation>
        <xs:complexType>
          <xs:sequence>
            <xs:element name="id" type="xs:string"/>
            <xs:element name="location" type="xs:string"/>
            <xs:element name="category" type="categoryType" minOccurs="0"/>
            <xs:element name="parent" type="xs:string" minOccurs="0"/>
            <xs:element name="related-to" type="xs:string" minOccurs="0"/>
            <xs:element name="meta" type="xs:string" minOccurs="0"/>
          </xs:sequence>
        </xs:complexType>
      </xs:element>
      <xs:element name="properties">
        <xs:annotation>
          <xs:documentation>Media properties</xs:documentation>
        </xs:annotation>
      </xs:element>
    </xs:sequence>
  </xs:complexType>
</xs:element>
```
<xs:complexType>

8.1 General Description of the Tool

8.1.1 Template Editor
The Template Editor is integrated within the AXMEDIS SMIL Editor and allows user to create new templates or modify existing ones. The creation of new templates is executed through the creation of a SMIL document: when the new SMIL document is completed, user can save resulting template and style-sheet. Template and style-sheet are obtained from the SMIL document with the application of an XSL Transformation (see formal description of gentemplate.xsl and genstyle.xsl).

When an existing template is opened, it is displayed with “fake” resources (which may be replaced later with real resources) and it is managed as a normal SMIL document.

8.1.2 Template Selector
The user interface of this Tool also allows an interactive template selection: user selects resources that have to be formatted, and obtains a list of suitable templates. Each template can be previewed and edited through the Template Editor.

The user should provide profiles for user preferences, device capabilities and delivery context: this can be done selecting existing files containing profile descriptors, or creating new descriptors via the user interface. A criteria indication is also needed: the user can select one of the existing criteria or create a new one via user interace.

After template selection, the interactive formatting process continues through the Style Selector.

8.2 Module Design in terms of Classes
The following diagram describes use-cases of this tool:
8.3 User interface description

Module functionalities are available through the following menu items of the AXMEDIS SMIL editor:

- Menu -> File -> Save template as...
- Menu -> File -> Open template...: open an existing template, showing “fake” resources
- Menu -> File -> New user profile...: allows to create a new XML user profile descriptor
- Menu -> File -> New device profile...: allows to create a new XML device profile descriptor
- Menu -> File -> New context profile...: allows to create a new XML context profile descriptor
- Menu -> File -> New criteria...: allows to create a new set of weights
- Menu -> Tools -> Set resources...: allows to specify resources that have to be formatted; for each resource, the author should specify its category of destination (e.g.: header, body, etc.)
- Menu -> Tools -> Template selector...: allows interactive selection of templates for the given resources (or “fake” resources if real resources have not been selected); the selected template can be previewed as-is, or after the style-sheet application

8.4 Formal description of format

8.4.1 Formal description of gentemplate.xsl

```xml
<?xml version="1.0" encoding="ISO-8859-1"?>
<!--
This style-sheet processes a complete SMIL document and creates an AXMEDIS template.
Author: Paolo Vaccari <vaccari@dsi.unifi.it>
-->

9.1 General Description of the Tool

9.1.1 Style Editor
The Style Editor is integrated within the AXMEDIS SMIL Editor and allows user to create new style-sheets or modify existing ones.

The creation of new style-sheets is executed through the creation of a SMIL document: when the new SMIL document is completed, user can save resulting template and style-sheet. Template and style-sheet are obtained from the SMIL document with the application of an XSL Transformation (see formal description of gentemplate.xsl and genstyle.xsl).

An existing style-sheet can be opened only in association with its related template; the result is displayed with “fake” resources (which may be replaced later with real resources) and it is managed as a normal SMIL document.

In both cases, user may mark some SMIL attributes as “optimizable”: the editor creates parameters in the resulting style-sheet and uses such parameters as attribute values.

9.1.2 Style Selector
The user interface of this Tool also allows an interactive style-sheet selection: user first selects resources that have to be formatted, then chooses a template using the Template Selector, finally uses the Style Selector to get a list of style-sheets suitable for the template.

A criteria indication is also needed: the user can select one of the existing criteria or create a new one via user interface.

Each style-sheet can be previewed and edited through the Style Editor, if it doesn’t contain parameters. Otherwise, the interactive formatting process must continue with the Style Optimizer.
9.2 Module Design in terms of Classes

The following diagram describes use-cases of this tool:

9.3 User interface description

Module functionalities are available through the following menu items of the AXMEDIS SMIL editor:

- Menu -> File -> Save style-sheet as...
- Menu -> File -> Open style-sheet... : open an existing style-sheet, if a template has already been selected
- Menu -> File -> New criteria... : allows to create a new set of weights
- Menu -> Tools -> Style-sheet selector... : allows interactive selection style-sheets for the given template and resources (or "fake" resources if real resources have not be selected)

9.4 Formal description of format

9.4.1 Formal description of genstyle.xsl

10.1 General Description of the Module
The Style Optimizer is integrated within the AXMEDIS SMIL Editor and allows user to get optimized value for parameters defined in the selected style-sheet. User may accept proposed values or set custom values.

10.2 Module Design in terms of Classes
The following diagram describes use-cases of this tool:

10.3 User interface description
Module functionalities are available through the following menu items of the AXMEDIS SMIL editor:
- Menu -> File -> New criteria...: allows to create a new set of weights
- Menu -> Tools -> Optimizer...: allows optimization of the selected style-sheets; optimized values are proposed to the user, who may change them and use custom values

11.1 General Description of the Module

In addition to using the engine's built-in objects, it is possible to create, initialize, and use own JS objects and JS Functions. This is especially true if the JS engine is used with scripts to automate the application. Custom JS objects can provide direct program services, or they can serve as interfaces to program's services. For example, a custom JS object that provides direct service might be one that handles all of an application's network access, or might serve as an intermediary broker of database services. Or a JS object that mirrors data and functions that already exist in the application may provide an object-oriented interface to C code that is not otherwise, strictly-speaking, object-oriented itself. Such a custom object acts as an interface to the application itself, passing values from the application to the user, and receiving and processing user input before returning it to the application. Such an object might also be used to provide access control to the underlying functions of the application.

There are two ways to create custom objects that the JS engine can use:

- Write a JS script that creates an object, its properties, methods, and constructor, and then pass the script to the JS engine at run time.
- Embed code (wrapping) in the application that defines the object's properties and methods, call the engine to initialize a new object, and then set the object's properties through additional engine calls. An advantage of this method is that the application can contain native methods that directly manipulate the object embedding.
11.2 A JavaScript class and functions in C++

In this section is reported an example of how to wrap a C++ class by embedding code without using inheritance ([2], [3]). For more details about JS API please see the official site of SpiderMonkey on Mozilla web page. The class used in the example is the following:

```cpp
class Customer
{
  public:
    int GetAge() { return m_age; }
    void SetAge(int newAge) { m_age = newAge; }
    std::string GetName() { return m_name; }
    void SetName(std::string newName) { m_name = newName; }
  
  private:
    int m_age;
    std::string m_name;
};
```

11.2.1 Step 1 - The JavaScript class.

Create a new C++ class that derives from the C++ class you want to use in JavaScript or create a new C++ class which has a member of the type of that C++ class.

A class is defined in JavaScript with a JSClass structure. Create a static member of this type. Declare it as a public member, because this structure can be useful for other classes. It can be used by other classes to determine the type of an object. (see JS_InstanceOf API)

```cpp
// JSCustomer.h
class JSCustomer
{
  public:
    JSCustomer() : m_pCustomer(NULL)
    {
    }

    ~JSCustomer()
    {
      delete m_pCustomer;
      m_pCustomer = NULL;
    }

    static JSClass customerClass;

  protected:
    void setCustomer(Customer *customer)
    {
      m_pCustomer = customer;
    }

    Customer* getCustomer()
    {
      return m_pCustomer;
    }

  private:
    Customer *m_pCustomer;
};
```

The JSClass structure contains the name of the JavaScript class, some flags and the name of callbacks used by the engine. For example a callback is used when the engine needs to retrieve a property from your class. Define the JSClass structure in the implementation file of the C++ class as below.

```cpp
// JSCustomer.cpp
JSClass JSCustomer::customerClass =
{
  "Customer", JSCLASS_HAS_PRIVATE,
  JS_PropertyStub, JS_PropertyStub,
  JSCustomer::JSGetProperty, JSCustomer::JSSetProperty,
  JS_EnumerateStub, JS_ResolveStub,
  JS_ConvertStub, JSCustomer::JSDestructor
};
```
The used callbacks are JSCustomer::JSGetProperty, JSCustomer::JSSetProperty and JSCustomer::JSDestructor. JSGetProperty is called when the engine needs a property, JSSetProperty is called when the engine sets a property and JSDestructor is called when the JavaScript object is destroyed. The flag JSCLASS_HAS_PRIVATE is used so that the engine provides memory you can use to attach some data to a JavaScript object. You can use this to store a pointer to your class. The callbacks are static member functions of the C++ class.

```cpp
static JSBool JSGetProperty(JSContext *cx, JSObject *obj, jsval id, jsval *vp);
static JSBool JSSetProperty(JSContext *cx, JSObject *obj, jsval id, jsval *vp);
static JSBool JSCustomer::JSDestructor(JSContext *cx, JSObject *obj, uintN argc,
                                       jsval *argv, jsval *rval);
static JSObject *JSCustomer::JSInit(JSContext *cx, JSObject *obj, JSObject *proto);
```

### 11.2.2 Step 2 - Initialize your JavaScript object

Create another static method called JSInit. See below for an example. This method will be called by the Application that creates the JavaScript runtime.

```cpp
static JSObject *JSCustomer::JSInit(JSContext *cx, JSObject *obj, JSObject *proto)
{
    JSObject *newObj = JS_InitClass(cx, obj, proto, &customerClass,
                                     JSCustomer::JSConstructor, 0,
                                     NULL, JSCustomer::customer_methods,
                                     NULL, NULL);
    JS_DefineProperties(cx, newObj, JSCustomer::customer_properties);
    return newObj;
}
```

The static method JSConstructor will be called when your object is instantiated in a script. This method is very handy to attach your data to the object using the JS_SetPrivate API.

```cpp
JSBool JSCustomer::JSConstructor(JSContext *cx, JSObject *obj, uintN argc,
                                  jsval *argv, jsval *rval)
{
    JSCustomer *p = new JSCustomer();
    p->setCustomer(new Customer);
    JS_SetPrivate(cx, obj, p);
    return JS_TRUE;
}
```

This constructor method can have multiple arguments, which you can use to initialize your class. Now that you've created a pointer on the heap, you also need a way to destroy the pointer. This is done in the static method JSDestructor.

```cpp
void JSCustomer::JSDestructor(JSContext *cx, JSObject *obj)
{
    JSCustomer *p = JS_GetPrivate(cx, obj);
    delete p;
    p = NULL;
}
```

### 11.2.3 Step 3 - Adding properties

Add a static array member of the type JSPropertySpec. This array will contain the information of a property. Create also an enum for the property ids.

```cpp
static JSPropertySpec customer_properties[];
enum
{
    name_prop,
    age_prop
};
```
Initialize this array in the implementation file as follows

```cpp
JSPropertySpec JSCustomer::customer_properties[] = {
    { "name", name_prop, JSPROP_ENUMERATE },
    { "age", age_prop, JSPROP_ENUMERATE },
    { 0 }
};
```

The last element of the array must be a null element. Each element contains another array with 3 elements. The first element is the name that will be used in JavaScript. The second is a unique id for the property. This will be passed to the callback functions. And the third one is a flag. JSPROP_ENUMERATE means that a script will see this property when it's enumerating the properties of the Customer object. You can also specify JSPROP_READONLY to indicate that the property can't be changed in the script.

Now you can implement the callbacks for getting and setting properties.

```cpp
JSBool JSCustomer::JSGetProperty(JSContext *cx, JSObject *obj, jsval id, jsval *vp)
{
    if (JSVAL_IS_INT(id))
    {
        Customer *priv = (Customer *) JS_GetPrivate(cx, obj);
        switch(JSVAL_TO_INT(id))
        {
            case name_prop:
                break;
            case age_prop:
                *vp = INT_TO_JSVAL(priv->getCustomer()->GetAge());
                break;
        }
    }
    return JS_TRUE;
}

JSBool JSCustomer::JSSetProperty(JSContext *cx, JSObject *obj, jsval id, jsval *vp)
{
    if (JSVAL_IS_INT(id))
    {
        Customer *priv = (Customer *) JS_GetPrivate(cx, obj);
        switch(JSVAL_TO_INT(id))
        {
            case name_prop:
                break;
            case age_prop:
                priv->getCustomer()->SetAge(JSVAL_TO_INT(*vp));
                break;
        }
    }
    return JS_TRUE;
}
```

It's recommended to return JS_TRUE in the property callbacks. When you return JS_FALSE a prototype will not be searched when the property is not found in your object.

### 11.2.4 Step 4 - Adding methods

Create a static member array of JSFunctionSpec type.

```cpp
static JSFunctionSpec customer_methods[];
```

Initialize this array in the implementation file as follows

```cpp
JSFunctionSpec wxJSFrame::wxFrame_methods[] = {
    { "computeReduction", computeReduction, 1, 0, 0 },
    { 0 }
};
```

The last element of the array must always be a null element. Each element is another array with 5 elements. The first element is the name of the method that's used in the script. The second one is the name of a global
or static member function. The third element is the number of arguments of this method. The last two elements are ignored.

Create a static method in the class

```cpp
static JSBool computeReduction(JSContext *cx, JSObject *obj, uintN argc,
                               jsval *argv, jsval *rval);
```

You return JS_TRUE when the function is successful. Otherwise you return JS_FALSE. The actual return of your JavaScript method is placed in the rval argument.

A sample implementation of this method

```cpp
JSBool JSCustomer::computeReduction(JSContext *cx, JSObject *obj, uintN argc,
                                     jsval *argv, jsval *rval)
{
    JSCustomer *p = JS_GetPrivate(cx, obj);
    if ( p->getCustomer()->GetAge() < 25 )
        *rval = INT_TO_JSVAL(10);
    else
        *rval = INT_TO_JSVAL(5);
    return JS_TRUE;
}
```

### 11.2.5 An example

The following script uses the previously created object

```javascript
var c = new Customer();
c.name = "Franky";
c.age = 32;
var reduction = c.computeReduction();
```

Don't forget to initialize the JavaScript object when you create the context:

```cpp
JSObject *obj = JSCustomer::JSInit(cx, global);
```

### 11.2.6 Wrapping functions

To wrap a native function you use JS_DefineFunction or to register multiple functions with one API call JS_DefineFunctions.

```cpp
/* Define a bunch of native functions first: */
static JSBool
my_abs(JSContext *cx, JSObject *obj, uintN argc, jsval *argv, jsval *rval)
{
    jsdouble x, z;
    if (!JS_ValueToNumber(cx, argv[0], &x))
        return JS_FALSE;
    z = (x < 0) ? -x : x;
    return JS_NewDoubleValue(cx, z, rval);
}
```

```cpp
/* Use a JSFunctionSpec array terminated with a null name to define a
 * bunch of native functions. */
static JSFunctionSpec my_functions[] = {
    /* name          native          nargs    */
    {"abs",         my_abs,         1},
    {"acos",        my_acos,        1},
    {"asin",        my_asin,        1},
    {0}
};
```

```cpp
/* Pass a particular object to define methods for it alone. If you pass
 * a prototype object, the methods will apply to all instances past and
 * future of the prototype's class (see below for classes). */
```
11.3 JSAXOM: AXMEDIS Data Model JS wrapping (DSI)

The JSAXOM models a set of JS Classes that wrap the main classes of the AXMEDIS Object Model. It includes the:

- JSAxObject for managing an instance of the AXMEDIS Object
- JSAxInfo for managing the metadata of the AXInfo section.
- JSAxResource for managing digital resources embedded or to be embedded in the AXMEDIS Object.
- JSAxDublinCore for managing an instance of Dublin Core metadata section
- JSAxMetadata for managing an instance of an AxMetadata object to cope with generic metadata

11.3.1 Module Design in terms of Classes

In this section the Axmedis Data Model wrapping for the Javascript and the current class diagram are reported.

**UML Class Diagram of JSAxClasses for the AXMEDIS Data Model in Javascript**

**JSaxBaseObject Class** – This class is the base class for JSAxObject, JSAxDublinCore, JSAxMetadata, JSAxInfo and JSAxResource classes. It allows linking them to the current instance of the Axmedis Object Manager (theAxom) and accessing to its methods and commands. It allows also to associate a reference to the AxIndex (AxIndex) with the current instance of a child class when it is inserted into the Axmedis Object Data Model. The isRoot attribute is set at TRUE when the instance refers to the root object of the Axmedis Object Data Model.
JSAxResource Class — The class models the AxResource type of the Axmedis Framework, it is used to store digital resource (audio, video, image, text, etc.) both raw data and Axmedis digital component. This class wraps the AxResource class and provides functionalities exposing setter and getter methods to:

- access to the mime type
- access to the byte stream of the resource
- create a new resource and to embed a file or a reference inside a resource object
JSAxObject Class – It is the mapping of an AXMEDIS Object for JavaScript. According to the specification of the AXMEDIS OBJECT MANAGER and Axmedis Data Model, it provides and wraps methods to:

- Create an empty AXMEDIS object with own AXOM by instantiating a new Axmedis Object.
- Create and fill an AXMEDIS object with own AXOM by loading content from an URL.
- Add/Remove an Element/Object to the AXMEDIS object. The addition of an element returns the new object reference inside the Axmedis Object.
- Get all Elements/Objects. It returns a Javascript array of Element/Objects.
- Add Resource, it adds a digital resource (audio, video, text, etc…) to a specific Element/Object. It returns the new resource object reference inside the Axmedis Object.
- Remove a Resource (audio, video, text, etc…) by using the object Resource reference.
- Get Resources. It returns a Javascript array of Resource objects.
- Add an AXInfo, Dublin Core or generic metadata object. It returns the new metadata object reference inside the Axmedis Object.
- Get the AXInfo, the Dublin Core metadata
- Remove any metadata object.

```javascript
const JSAxObject = {
  addObject: function (obj) {
    // Add object to the Axmedis Object
    // obj: the object to add
  },
  removeObject: function (obj) {
    // Remove object from the Axmedis Object
    // obj: the object to remove
  },
  addResource: function (resource) {
    // Add resource to the Axmedis Object
    // resource: the resource to add
  },
  removeResource: function (resource) {
    // Remove resource from the Axmedis Object
    // resource: the resource to remove
  },
  addAXInfo: function (axInfo) {
    // Add AXInfo to the Axmedis Object
    // axInfo: the AXInfo object
  },
  removeAXInfo: function (axInfo) {
    // Remove AXInfo from the Axmedis Object
    // axInfo: the AXInfo object
  },
}
```

AXMEDIS Project 183
JSAxInfo Class – It maps and allows managing the metadata of the AXINFO in the JavaScript. This class manages the access to individual elements and fields in AXINFO metadata, this class map all the functionalities provided by AxInfo class exposing setter and getter methods for accessing to data. It allows to manage:

- ObjectCreator information
- Owner information
- Distributor information
- Object Status information
- PromoOf information
- Workflow information
- Fingerprint information
- PAR information

JSAxDublinCore Class - The class models the AxDublinCore type of the Axmedis Framework, it is used to store metadata in Dublin Core format. This class d provides functionalities exposing setter and getter methods to:

- retrieve the description of metadata
- to store the metadata
- to get the number of elements
- to remove an element

JSAxMetadata Class - The class models the AxMetadata type of the Axmedis Framework, it is used to store metadata in XML format. This class d provides functionalities exposing setter and getter methods to:

- retrieve the XML description of metadata
- to store the XML of metadata
11.3.2 Draft User Manual

In this section a draft description of the JSAXOM classes is provided in terms of Javascript language. For each class the set of exposed attributes, constructors and methods are reported.

**JSAxObject**

The Class name in the Javascript is *AxmedisObject*

**Exposed properties**

- **string AXOID**
  It provides the current axoid

- **number childrenCount**
  It represents the number of Children items

- **string URI**
  Where the object is located

- **string contentID**
  The content identifier

**Exposed methods**

- **AxmedisObject()**
  Empty constructor for an empty AXMEDIS Object.

- **AxmedisObject (string URI)**
Constructors with an URI parameter. The Axmedis Object is loaded by using the URI. It can specify a file system or a database location.

`addMetadata(AxInfo obj)`
- It adds an `AxInfo` metadata object.

`addMetadata(AxDublinCore obj)`
- It adds an `AxDublinCore` metadata.

`addMetadata(AxMetadata obj)`
- It adds an `AxMetadata` object.

`array getGenericMetadata()`
- It returns an array of generic metadata objects or null.

`AxDublinCore getDublinCore()`
- It returns an `AxDublinCore` metadata object.

`AxInfo getAxInfo()`
- It returns an `AxInfo` metadata object.

`removeMetadata (AxInfo obj)`
- It removes an `AxInfo` metadata object.

`removeMetadata (AxDublinCore obj)`
- It removes an `AxDublinCore` metadata.

`removeMetadata (AxMetadata obj)`
- It removes a generic metadata object.

`addContent(AxResource res)`
- It adds an `AxResource` content instance.

`addContent(AxmedisObject res)`
- It adds an `AxmedisObject` content instance.

`addContent(Document res)`
- It adds a Document coming from Searchbox tool transforming it in `AxResource`.

`array getContent()`
- It returns an array of `AxResource` and `AxmedisObject` content or null.

`removeContent (AxResource res)`
- It deletes an existing `AxResource` content instance.

`removeContent (AxmedisObject res)`
- It deletes an existing `AxmedisObject` content instance.

`save(string path)`
- It saves the axmedis object onto filesystem.

`uploadToDB(string URI)`
- It uploads the axmedis object into database at the specified URI.

`obtainDefinitiveAXOID()`
The AXMEDIS Object is univocally defined by asking for a Definitive AXOID

`registerToAXCS()`
The AXMEDIS Object is registerd to AXCS.

**JSAxInfo**
Class name in the Javascript is *AxInfo*

**Exposed properties**

//Contributor
`number objectContributorCount`
the number of ObjectContributor present

//Owner section
`string ownerID`
the code identifying the owner

`string ownerIDCoding`
coding used to identify the owner

`string ownerName`
the name of the owner

`string ownerURL`
URL of the owner

`string ownerCompany`
company of the owner

`string ownerCompanyUrl`
company URL of the owner

`string ownerNationality`
nationality of the owner

// Distributor section
`number distributorCount`
number of Distributors present

// Object Status section
`string objectAccessMode`
the access mode: “READ_ONLY” or “READ_WRITE” string.

`Date objectCreationDate`
the local date and time of object creation

`Date objectLastModificationDate`
the local date and time of object modification

`number objectVersion`
version of the object

`number objectRevision`
revision of the object

string objectStatus
    current status of the object

string objectType
    object type ("BASIC" or "COMPOSITE")

string objectProtectionStamp
    the protection stamp

// PromoOf section
number promoOfAXOIDCount
    count of AXOID in the PromoOf section

// Workflow section
string workflowItemID
    WorkflowWorkItemID

string workflowWorkspaceInstanceID
    WorkflowWorkspaceInstanceID

// Internal PAR
boolean hasInternalPAR
    how many Internal PAR sections are present (0 or 1)

string internalPARStatus
    the internal PAR status

// PAR section
boolean hasPAR
    how many PAR sections are present (0 or 1)

string PARStatus
    the PAR status

string PARLicensingURL
    the licensing URL

// Status section
boolean isProtected
    if the object is protected or not. True means protected.

boolean isGoverned
    if the object contains a licence or not.

Exposed methods

AxInfo()
    Empty constructor

AxInfo(AxInfo info)
    Copy constructor. It create a copy of info object

ObjectContributor Management
number addObjectContributor(number pos)
  Adds a new ObjectContributor in the position given (starting from 0), position -1 means to add at the end. The return value indicates the position in which it is added.

removeObjectContributor (number pos)
  Removes an ObjectContributor from the position specified

number getObjectContributorCount()
  Returns the number of ObjectContributor present

number findObjectContributorByAXCID(string axcid)
  Returns the position of an ObjectContributor with a specific AXCID. It returns -1 if not found.

number findObjectContributorByName(string nam)
  Returns the position of an ObjectContributor with a specific Name. It returns -1 if not found.

string getObjectContributorAXCID(number refNum)
  allow getting the AXCID value for an ObjectContributor identified by position refNum

setObjectContributorAXCID(number refNum, string axcid)
  allow setting the AXCID value for an ObjectContributor identified by position refNum

string getObjectContributorName(number refNum)
  allow getting the Name value for an ObjectContributor identified by position refNum

setObjectContributorName(number refNum, string name)
  allow setting the Name value for an ObjectContributor identified by position refNum

string getObjectContributorURL(number refNum)
  allow getting the URL value for an ObjectContributor identified by position refNum

setObjectContributorURL(number refNum, string URL)
  allow setting the URL value for an ObjectContributor identified by position refNum

string getObjectContributorCompany(number refNum)
  allow getting the Company value for an ObjectContributor identified by position refNum

setObjectContributorCompany(number refNum, string company)
  allow setting the Company value for an ObjectContributor identified by position refNum

string getObjectContributorCompanyURL (number refNum)
  allow getting the CompanyURL value for an ObjectContributor identified by position refNum

setObjectContributorCompanyURL(number refNum, string URL)
  allow setting the CompanyURL value for an ObjectContributor identified by position refNum

string getObjectContributorNationality(number refNum)
  allow to get and set the Nationality value for an ObjectContributor identified by position refNum

setObjectContributorNationality(number refNum, string nationality)
  allow setting the Nationality value for an ObjectContributor identified by position refNum

Owner Management

string getOwnerID()
allow getting the code identifying the owner

setOwnerID(string value)
allow setting the code identifying the owner

string getOwnerIDCoding()
allow getting the coding used to identify the owner

setOwnerIDCoding(string value)
allow setting the coding used to identify the owner

string getOwnerName()
allow getting the name of the owner

setOwnerName(string value)
allow setting the name of the owner

string getOwnerURL()
allow getting the URL of the owner

setOwnerURL(string value)
allow setting the URL of the owner

string getOwnerCompany()
allow getting the company of the owner

setOwnerCompany(string value)
allow setting the company of the owner

string getOwnerCompanyURL()
allow getting the company URL of the owner

setOwnerCompanyURL(string value)
allow setting the company URL of the owner

string getOwnerNationality()
allow getting the nationality of the owner

setOwnerNationality(string value)
allow setting the nationality of the owner

number addOwnerDescription(number pos)
adds a new description of the owner at the position specified or at the end if position is -1. The return value indicates the position where it is added.

removeOwnerDescription(number pos)
removes the description specified

string getOwnerDescription(number pos)
allow getting the value of the description

setOwnerDescription(number pos, string description)
allow setting the value of the description

string getOwnerDescriptionLanguage(number pos)
allow getting the value of the description language

```java
setOwnerDescriptionLanguage(number pos, string description)
```

allow setting the value of the description language

**Distributor Management**

```java
addDistributor()
```

adds a Distributor if not present.

```java
removeDistributor()
```

removes the Distributor

```java
number getDistributorCount()
```

returns the number of Distributors present

```java
string getDistributorAXDID()
```

allow getting the AXDID value for the Distributor

```java
setDistributorAXDID(string value)
```

allow setting the AXDID value for the Distributor

```java
string getDistributorName()
```

allow getting the Name value for the Distributor

```java
setDistributorName(string value)
```

allow setting the Name value for the Distributor

```java
string getDistributorURL()
```

allow getting the URL value for the Distributor

```java
setDistributorURL(string value)
```

allow setting the URL value for the Distributor

```java
string getDistributorNationality()
```

allow getting the Nationality value for the Distributor

```java
setDistributorNationality(string value)
```

allow setting the Nationality value for the Distributor

**Object Status**

```java
string getAccessMode()
```

it returns the access mode: “READ_ONLY” or “READ_WRITE” string.

```java
setAccessMode(string value)
```

allow setting the Access the object specifying strings “READ_ONLY” or “READ_WRITE”

```java
Date getCreationDate()
```

get the local date and time of object creation

```java
Date getLastModificationDate()
```

get the local date and time of object modification

```java
number getVersion()
```

get the version of the object
number getRevision()
get the revision of the object

string getObjectType()
allow to get object type ("BASIC" or "COMPOSITE")

boolean getIsProtected()
allows getting if the object is protected or not. True means protected.

void setObjectCreatorAXCID(string val)
allow setting the AXCID value for the ObjectCreator

void setObjectCreatorName(string name)
allow setting the Name value for the ObjectCreator

void setObjectCreatorURL(string url)
allow setting the URL value for the ObjectCreator

void setObjectCreatorCompany()

Object Creator Management

allow getting the Company value for the ObjectCreator

```java
setObjectCreatorCompany(string company)
```
allow setting the Company value for the ObjectCreator

```java
string getobjectCreatorCompanyURL()
```
allow getting the CompanyURL value for the ObjectCreator

```java
setObjectCreatorCompanyURL(string URL)
```
allow setting the CompanyURL value for the ObjectCreator

```java
string getobjectCreatorNationality()
```
allow getting the the Nationality value for the ObjectCreator

```java
setObjectCreatorNationality(string nationality)
```
allow setting the Nationality value for the ObjectCreator

**PromoOf Management**

```java
addPromoOfAXOID(string axoid, number position)
```
adds a new AXOID in the PromoOf section, the position indicates where to put the AXOID, -1 means at the end

```java
removePromoOfAXOID(number position)
```
removes the AXOID in the position specified

```java
number getPromoOfAXOIDCount()
```
get the count of AXOID in the PromoOf section

```java
string getPromoOfAXOID(number position)
```
allow getting the AXOID in a specified position

```java
setPromoOfAXOID(number position, string value)
```
allow setting the AXOID in a specified position

**Workflow Status**

```java
string getWorkflowWorkItemID()
```
allow getting the WorkflowWorkItemID

```java
setWorkflowWorkItemID (string value)
```
allow setting the WorkflowWorkItemID

```java
string getWorkflowWorkspaceInstanceID()
```
allow getting the WorkflowWorkspaceInstanceID

```java
setWorkflowWorkspaceInstanceID (string value)
```
allow setting the WorkflowWorkspaceInstanceID

**Internal Potential Available Rights Management**

```java
addInternalPotentialAvailableRights()
```
adds a new Internal PAR section

```java
removeInternalPotentialAvailableRights()
```
removes the Internal PAR section

```java
getInternalPotentialAvailableRightsCount()
```
gets how many Internal PAR sections are present (0 or 1)

```java
string getInternalPotentialAvailableRightsStatus()
    allow getting the internal PAR status

setInternalPotentialAvailableRightsStatus(string value)
    allow setting the internal PAR status

License getInternalPotentialAvailableRightsLicense()
    gets the license
```

**Potential Available Rights Management**

addPotentialAvailableRights()
    adds a new PAR section if not present

removePotentialAvailableRights()
    removes the PAR section

generatePotentialAvailableRightsCount()
    gets how many PAR sections are present (0 or 1)

```java
string getPotentialAvailableRightsLicensingURL()
    allow getting the licensing URL

setPotentialAvailableRightsLicensingURL (string value)
    allow setting the licensing URL

string getPotentialAvailableRightsStatus()
    allow getting the PAR status

setPotentialAvailableRightsStatus(string value)
    allow setting the PAR status

License getPotentialAvailableRightsLicense()
    gets the license
```

**Object History Management**

string getHistoryOfVersion(number version)
    gets the history of a version as an XML string

**JSAXResource**

Class name in the Javascript is AxResource

**Exposed attributes**

```java
string mimeType
    The MimeType associated with the extension of digital resource

string ref
    reference

string contentID
    content identifier

string encoding
```

**AXMEDIS Project**
encoding type

**Exposed methods**

*load (string path)*  
It loads a Raw Resource from filesystem

*save (string path)*  
It saves a Raw Resource onto filesystem

**JSAxDublinCore**
Class name in the Javascript is *AxDublinCore*

**Exposed properties**

*string metadataID*

**Exposed methods**

*addDCElement(string type, string value, string language)*  
Add a new element specifying type, value and language

*addDCElement(string type, string value)*  
Add a new element specifying type, value. The language has an empty value

*removeDCElement(string type, number refNum)*  
Delete an element specifying type and reference number.

*string getDCElementValue(string type, number refNum)*  
Return an element specifying type and reference number.

*string getDCElementValue(string type)*  
Return an element specifying type. The reference number is 0

*setDCElementValue(string type, number refNum, string value)*  
Modify the element specifying type, reference number and value

*string getDCElementLanguage(string type, number refNum)*  
Return the language of the element specifying type and reference number.

*string getDCElementLanguage(string type)*  
Return the language of the element specifying type. The reference number is 0

*setDCElementLanguage(string type, number refNum, string language)*  
Modify the language of element specifying type, reference number and language

*number getDCElementCount(string type)*  
Return the number of elements specifying type.

**JSAxMetadata**
Class name in the Javascript is *AxMetadata*

**Exposed properties**
string namespace
The used namespace in the XML description. It is a readonly attribute.

Exposed methods

AxMetadata()
Empty constructor

AxMetadata(string xml)
Constructor with parameter. It builds an object storing the XML passed as a string

addXML(string xml)
It stores an XML description of metadata passed as a string

string getXML()
It returns the string with XML of the metadata description

11.3.3 Examples of usage

// Function for creating the Dublin Core information
function createDC(obj,title)
{
    dc = obj.getDublinCore();
    dc.addDCElement("creator","AXCP Rule Editor");
    dc.addDCElement("title",title);
    dc.addDCElement("type","conversion to "+format);
    dc.addDCElement("description","Testing JSScript with resized and converted images");
}

function adaptAxImages(axobj,height,width,mimeType)
{
    print("Creating adapted image");
    var h1 = new Array(1);
    var w1 = new Array(1);
    h1[0]=0;
    w1[0]=0;
    var resource = axobj.getContent();
    var i = 0;
    for (i in resource)
    {
        var res = resource[i];
        val = resource[i].mimeType.search("image");
        if(val==0)
        {
            ImageProcessing.GetInfo(resource[i],h1,w1);
            print("Original resource size is "+h1[0]+"x"+w1[0]);
            print("Resizing the resource at "+height+"x"+width);
            ImageProcessing.Resize(resource[i],height,width,false,resource[i]);
            ImageProcessing.GetInfo(resource[i],h1,w1);
            print("New resource size is "+h1[0]+"x"+w1[0]);
            if(resource[i].mimeType != format)
            {
                print("Converting the resource in "+format);
                ImageProcessing.Conversion(resource[i],mimeType,resource[i]);
            }
        }
    }
}

function cloneAxmedisObject(sourceObj,targetObj)
{
    var metadata = sourceObj.getGenericMetadata();
    if(metadata!=null)
    {
        for(j in metadata)
        {
            ...
        }
    }
}

AXMEDIS Project
targetObj.addMetadata(metadata[j]);
}
targetObj.addMetadata(sourceObj.getAxInfo());
var resources = sourceObj.getContent();
if(resources!=null)
{
    for(k in resources)
        targetObj.addContent(resources[k]);
}

// Function for creating the Axmedis Object by composing and converting resources
function test()
{
    var imgFormat = getMimeType(format);
    selection.resolveQuery("test","test",0);
    var documentList = selection.getAXDBResult();
    for (i in documentList)
    {
        uri ="axdb://"+documentList[i];
        var axmedisObject = new AxmedisObject(uri);
        var dublinCore = axmedisObject.getDublinCore();
        var title = dublinCore.getDCElementValue("title")+"_Resized";
        var newObj = new AxmedisObject();
        cloneAxmedisObject(axmedisObject, newObj);
        createDC(newObj, title);
        adaptAxImages(newObj, h, w, imgFormat);
        print("Storing Object on disk");
        newObj.save(resourcePath+title+'.axm');
    }
    return true;
}

//Entry point of the script
test();

11.3.4 Technical and Installation information
The JS Class comes in the form of a static LIB.

| References to other major components needed | |
| Problems not solved | |
| Configuration and execution context | It is used within the AXCP Rule Editor and Engine. |

Information about the installation of JS modules within the AXCP Rule Editor and Engine can be found in section “AXMEDIS DATA Types and Functions for JavaScript”.

JSAXCPlugin is a metaclass that refers and wraps dynamically AXMEDIS Content Processing Plugins. It provides and manages the access to the set of functions exposed by DLLs discovered by the Plugin Manager and related to AXMEDIS content production, protection, adaptation algorithms and tools. Dependencies of the rule define the number of and what plugins have to be loaded at the start of the execution, each plugin is a global instance of the AxCPPlugin class and the name of the instance is the same of the plugin.

Functions provided by the Axmedis Plugins for content processing

- Fingerprint functions
- Digital Resource Adaptation functions
- Protection functions
- Metadata Adaptation functions
- Functions for using External tools

11.4.1 Module Design in terms of Classes

```javascript
JSAXCPlugin
+AxCPPlugin class : JClass =
  'AxCPPlugin', JCLASS_HAS_PRIVATE, JS_PropertyStub, JS_PropertyStub,
  JS_PropertyStub, JS_PropertyStub,
  JS_EnumerateStub, JSResolveStub, JS_ConvertStub, JSAXCPlugin, JSDestructor
+AxCPPlugin proto : JObject * = NULL
+m_AxCPPluginId: string
-AxCPPlugin_methods : JFunctionSpec *
-resCount : int = 0
+JSAXCPlugin()
+-JSAXCPlugin()
+JSDestructor(in cx : JSContext, in obj : JObject)
+JSInit(in cx : JSContext, in obj : JObject*, in proto : JObject* = 0), JObject*
+convertAxCPParameter2JSVAL(in cx : JSContext, in result : AxCPParameter*, jsval
+setAxCPPluginId(in pluginId : string)
+getAxCPPluginId() : string
```

11.4.2 Draft User Manual

JSAXCPlugin

The Class name in Javascript is AxCPPlugin. This class is instantiated every time a dependency is defined in the rule. The allocation is performed automatically by the engine, the user can use such instance directly by means the name of the dependency (plugin) as an object. The class does not provide any attributes, but it is populated at runtime with methods that map the plugin functions. So that, dot notation is available for
invoking such functions and each function can be call by passing the input/output parameters. The signature of the function is specified in the plugin profile XML description, see the example for more details.

11.4.3 Examples of usage
In the example below, the excerpt of JS script shows how to use a function of the ImageProcessing Plugin

```javascript
var imgResource = new AxResource()
    imgResource.load(resourcePath+resName);
if(imgResource.mimeType.search("image")==0)
{
   ImageProcessing.Conversion(imgResource,format, imgResource);
   imgResource.save(outputPath+title);
}
```

In the excerpt, the "resourcePath", the "outputPath", "res" and "format" are parameters of the AXCP Rule and they contain actual values respectively stating for:
- **resourcePath** is the path on the filesystem where find the resource
- **outputPath** is the path on the filesystem where store the resource
- **resName** is the filename of the resource
- **format** is the output format (i.e. expressed as mimetype)

Finally, **title** is a variable defined in the script at runtime used to set the output name of the resource

For more details see also the example in the JSAXOM section.

11.4.4 Technical and Installation information
The JS Class comes in the form of a static LIB.

| References to other major components needed | |
| Problems not solved | |
| Configuration and execution context | It is used within the AXCP Rule Editor and Engine. |

Information about the installation of JS modules within the AXCP Rule Editor and Engine can be found in section “AXMEDIS DATA Types and Functions for JavaScript”.

JS connection classes are a set of Javascript classes that provide the communication support to the AXCP Engine by modeling in terms of primitive functionalities the network and database access. They consist in:

- **JSHttpConnection** The class models the http connection by providing primitive methods for accessing and retrieving information by means the http protocol

- **JSftpConnection** The class models the http connection by providing primitive methods for accessing and retrieving information by means the http protocol

- **JSodbcConnection** The class models the http connection by providing primitive methods for accessing and retrieving information by means the http protocol

- **JSwebServiceConnection** The class models a meta class for managing web services by loading WSDL description and dynamically creating services (methods).

- **JSForm** The class models a simple form of a http web page

### 11.5.1 Module Design in terms of Classes

In this section C++ connection classes are described. For each of them attributes and main methods are reported. Empty constructors and destructors are not listed, constructors that need input parameters are described. The following pictures describe the class diagrams.
Connection Class

This C++ class models a generalised network connection.

Attributes
- **UserId**: string – It is the username for login.
- **PassWord**: string – It is the password for login
- **Content**: string – It is the buffer where data is stored
- **Port**: int – It is the port number to use for the connection if it is different from the default port.

Methods
- **getResultMessage(): String** – It provides the result of the last operation. In event of success an Exit Success is returned otherwise the message string provides the type of fault.
- **setLogin(UserId: String, PassWord: String): bool** - It allows setting username and password for a login request.
- **getLogin(): bool** – It tests the login parameters. If they were set the method returns TRUE, FALSE otherwise.
- **clearLogin(): bool** – It clears the existing login parameters.
- **setPort(port: int): bool** – It allows setting a port different from the default.
- **clearPort(): bool** metodo - It clears the port number resuming the default port.

ftpConnection class

The ftpConnection specialises the Connection class. It allows performing download and upload file via ftp. It is necessary to provide the URL of the server where put/get the resource.

Attributes
No attributes
Methods

- `download(Url:String, FilePath:String):bool` – It performs the download of a file. The location of file is provided by the `Url` parameter, the file is stored on file system at the `FilePath` location.
- `upload(Url:String, FilePath:String):bool` – It allows uploading a file from the `FilePath` location on own file system into a `Url` of the ftp server.

httpConnection Class

The httpConnection specialises the Connection class It allows using the access on network by using the http protocol.

Attributes

No attributes

Methods

- `getInString(Url:String):bool` – It allows performing the GET command from the specified `Url`. Received data can be retrieved by using the `getContent()` method.
- `getInFile(Url:String, FilePath:String):bool` – It allows performing the GET command from the specified `Url`. Received data are written directly on a file specified by `FilePath` parameter.
- `putFromString(Url:String, Buffer:String):bool` – It allows performing the PUT http command to the specified `Url`. The `buffer` parameter contains data to be sent to the server.
- `putFromFile(Url:String, FilePath:String):bool` – It allows performing the PUT http command to the specified `Url`. The `FilePath` parameter contains the location of file to be sent to the server.
- `post(Url:String, PostContent:FormArray):bool` – It allows performing the POST http command to the specified `Url`. We suppose to use this command to send to the server contents of some form-fields inside a html page. Before using this command it is necessary to create an array of Form object to use with the POST command.

Form Class

This class models a form in terms of name, type and value.

Attributes

- `formName:String` – It is the name of the form
- `formType:String` – It is the type of form
- `formValue:String` – It is the value of form to post

WebDavConnection class

The WebDavConnection specialises the httpConnection class It allows using the access on network by using the main methods of the WebDav protocol.

Attributes

No attributes

Methods

- `mkCol(Url:String):bool` – It allows invoking the MKCOL Web-Dav. It creates a collection of resources at the specified `Url`.
- `Delete(Url:String):bool` – It allows invoking the DELETE Web-Dav. It deletes the resource in the specified `Url`.
- `propFind(Url:String, TagArray:StringArray):bool` – It allows invoking the PROPFIND WebDav. It retrieves properties of the resource associated with the specified `Url`. It is possible to query specific properties by listing them in `TagArray`. Invoking the methods without an empty `TagArray` returns all properties.
OdbcConnection Class
The OdbcConnection class allows accessing to a database via Odbc.

Attributes
No attributes

Methods
- `setDbConnection(OdbcSource:String, UserName:String, PassWord:String):bool` – It allows setting the connection parameters. It has to be called before opening a Database connection.
- `openDbConnection():bool` – It opens a Database connection after the call of `setDbConnection`.
- ` execQuery(query:String):bool` – It allows making a SQL query. Results are provided in a table and can be retrieved by calling the access methods: `nextRow` and `getRow`.
- `nextRow():bool` – It allows browsing the table of results row by row. It set the internal pointer to the current row.
- `getRow():StringArray` – It allows retrieving content from the last pointed row. Values are returned in an array of string. The length of the array depends on the number of column of the table.
- `getErrorMessage():String` – It returns the last error message.
- `closeDbConnection():bool` – It closes the Database connection.

WebServiceConnection Class
The class allows opening a WebService connection based on a Wsdl. It creates at run-time a WebService client that allows invoking operations defined by the wsdl. Each operation is called by providing input parameters and return a result as operation return value.

Attributes
No attributes

Methods
- `WebServiceConnection(WsdlSource:string)` – Constructor that create a WebServiceConnection object based on the specified `WsdlSource`. The source can be a file or Url.
- `getMethods():StringArray` – It returns an array where are stored the name of available operations.
- `getParamsNumber(MethodName:String):int` – It allows getting the number of required parameter for the operation specified in the `MethodName`.
- `getParamsType(MethodName:String):TypeArray` – It allows getting types of required parameters by the operation specified in the `MethodName`. Types are available in the `TypeArray` object.
- `call(MethodName:String, Params:StringArray):bool` – The method allows invoking an operation on WebService. The `MethodName` specifies the operation to call with the list of `Params`.
- `getResult():ValuesArray` – The method gets the result returned by the call. The result is stored in an array of Value (`ValuesArray`).
11.5.2 Draft User Manual
This is a draft User Manual for the JS classes.

**JSForm**

This class wraps the `Form` class. Class name in Javascript is `Form`.

**Exposed Properties**

- **string formName**
  - It is the name of the form

- **string formType**
  - It is the type of form

- **string formValue**
  - It is the value of form to post

**Exposed methods**

No methods
JShttpConnection
The class wraps the httpConnection class. Class name in Javascript is HttpConnection

Exposed methods

HttpConnection()
Create a new empty HttpConnection object

string getResultMsg()
Return the last Result Message: an Exit Success is returned otherwise the message string provides the type of fault.

string getContent()
Return the html page as string

setLogin(string username, string password)
Set the account parameter for login

boolean getLogin()
Get the status of Login parameters, it returns true if they are set, false otherwise.

clearLogin()
Reset the account parameters for login

setPort(string port)
set a Port at the port number value

clearPort()
Clear the port number resuming the default port.

getString(string url)
Get function, copy content at the specified url to a String. It is used in conjunction with getContent().

getToFile(string url, string filePath)
Get function, copy content at the specified url to a File at filePath

putFromFile(string url, string filePath)
Put function, put a content From a File at filePath to a specified url

putFromString (string url, string buffer)
Put function, put content From a String buffer to a specified url

post(string url, array jsform)
Post at the specified url the array of JSForm data It allows performing the POST http command to the specified Url. We suppose to use this command to send to the server contents of some formfields inside a html page. Before using this command it is necessary to create an array of JSForm object to use with the POST command.

JSftpConnection
Class name in Javascript is FtpConnection

Exposed methods
**FtpConnection()**
Create a new empty *FtpConnection* object

**string getResultMsg()**
Return the last Result Message: an *Exit Success* is returned otherwise the message string provides the type of fault.

**string getContent()**
Return the content as string

**setLogin(string username, string password)**
Set the account parameter for login

**boolean getLogin()**
Get the status of Login parameters, it returns *true* if they are set, *false* otherwise.

**clearLogin()**
Reset the account parameters for login

**setPort(string port)**
set a Port at the *port* number value

**clearPort()**
Clear the port number resuming the default port.

**download(string Url, string FilePath)**
It performs the download of a file. The location of file is provided by the *Url* parameter, the file is stored on file system at the *FilePath* location.

**upload(string Url, string FilePath)**
It allows uploading a file from the *FilePath* location on own file system into a *Url* of the ftp server.

**JSodbcConnection**
Class name in Javascript is *OdbcConnection*

**Exposed methods**

**OdbcConnection()**
Create a new empty *OdbcConnection* object

**setDbConnection(string OdbcSource, string UserName, string PassWord)**
It allows setting the connection parameters. It has to be called before opening a Database connection.

**openDbConnection()**
It opens a Database connection after the call of *setDbConnection*.

**execQuery(string query)**
It allows making a SQL query. Results are provided in a table and can be retrieved by calling the access methods: *nextRow* and *getRow*

**nextRow()**
It allows browsing the table of results row by row. It set the internal pointer to the current row.
**Array getRow()**

It allows retrieving content from the last pointed row. Values are returned in an array of string. The length of the array depends on the number of column of the table.

**String getErrorMessage()**

It returns the last error message.

**closeDbConnection()**

It closes the Database connection.

**JSwebServiceConnection**

Class name in Javascript is `WebServiceConnection`

**Exposed Properties**

**wsdlURI**

It is the URI used to load the WSDL

**Exposed methods**

`WebServiceConnection(string URI)`

Constructor method loads the WSDL specified by the URI string input parameter.

All other methods are defined dynamically according to the loaded WSDL,
All input parameters are string.

**11.5.3 Examples of usage**

```javascript
var ftp = new FtpConnection();
ftp.setLogin (UserName, PassWord);
ftp.download (URL, DestinationPath);
print(ftp.getResultMsg());

var http = new HttpConnection();
var content = new string();
http.setPort(80);
http.getToString(URL);
content = http.getContent();
print(content);

var formArray = new Array(2);
var content = new String();
formArray[0] = new Form("FormName", "FormType", "FormValue");
formArray[1] = new Form("FormName", "FormType", "FormValue");
http.post(URL, formArray);
content = http.getContent();
print(http.getContent());

var webDav = new WebDavConnection();
webDav.mkCol(URL);
content = webDav.getContent();
print(content);

var odbc = new OdbcConnection();
var RowArray = new Array(3) ;
odbc.setOdbcConnection(DbName, UserName, PassWord);
```
odbc.openDbConnection();
odbc.execQuery(QUER Y) ;
RowArray[0] = odbc.getRow();
odbc.nextRow();
RowArray[1] = odbc.getRow();
print(odbc.getErrorMsg());
odbc.closeDbConnection();

var Array = new Array();
var WebService = new WebServiceConnection(URL);
Array = WebService.generateAxoid("mario ", "xxxx", "Pluto");

11.5.4 Technical and Installation information
The JS Class comes in the form of a static LIB.

| References to other major components needed | |
| Problems not solved | |
| Configuration and execution context | It is used within the AXCP Rule Editor and Engine. |

Information about the installation of JS modules within the AXCP Rule Editor and Engine can be found in section “AXMEDIS DATA Types and Functions for JavaScript”.

JS_ZipArchiver class models Javascript class for creating archives of files based on the ZIP algorithm.
11.6.1 Module Design in terms of Classes

ZipArchiver Class

Attributes
zipFile: string
The string contains the file as array of chars

Methods
- createNewZipArchive(filePath: String): bool – It creates a new zip file at the filePath location. filePath has to contain the name of file.
- openZipArchive(filePath: String): bool – It opens an existing zip archive at the filePath location.
- addFileToZip(zipFilePath: String, filePath: String): bool - It adds a file at the filePath location to the zipFilePath archive.
- removeFileFromZip(fileName: String): bool – It deletes a fileName file from the archive.
• **unzip():bool** – It allows to unzip the archive in the same folder of the archive.

• **unzip(dirPath:String):bool** – It allows to unzip the archive in the *dirPath* folder.

### 11.6.2 Draft User Manual

This is a draft User Manual for the JS classes.

**JSZipArchiver**

Class name in Javascript = *ZipArchiver*

**Exposed methods**

**ZipArchiver()**

It creates a *ZipArchiver* object

**createNewZipArchive(string filePath)**

It creates a new zip file at the filePath location. *filePath* has to contain the name of file.

**openZipArchive(string filePath:String)**

It opens an existing zip archive at the filePath location.

**addFileToZip(string zipFilePath, string filePath)**

It adds a file at the *filePath* location to the *zipFilePath* archive.

**removeFileFromZip(string fileName)**

It deletes a *fileName* file from the archive.

**unzip()**

It allows to unzip the archive in the same folder of the archive.

**unzip(string dirPath)**

It allows to unzip the archive in the *dirPath* folder.

### 11.6.3 Examples of usage

```javascript
var Zipper = new ZipArchiver();
Zipper.createNewZipArchive ("C:/pippo.zip");
Zipper.addFileToZip ("C:/pluto.txt");

var Zipper = new ZipArchiver();
var FilesList = new Array();
FilesList[0]="C:/pippo.txt";
FilesList[1]="C:/minnie.txt";
Zipper.addFilesToZip ("pippo zip", FilesList);

var Zipper = new ZipArchiver();
Zipper.openZipArchive("C:/pippo.zip");
Zipper.unzip();
```

### 11.6.4 Technical and Installation information

The JS Class comes in the form of a static LIB.

</tbody>
</table>

The `JSAxSelection` class maps the `Selection` document in the JavaScript. This class allows using `Selection` objects
to manage the access and to make queries to the AXMEDIS database, and to retrieve AXMEDIS objects ID (AXOID).
It manages the array of AXOID provided by the MainQuerySupport when the selection is resolved to be actualized.

**11.7.1 Module Design in terms of Classes**
The `JSAxSelection` wraps the `AxSelectionDocument` class referring to it by means of the `m_pAxSelection` pointer.
11.7.2 Draft User Manual

This is a draft User Manual for the JSSelection class.

**JSxSelection**

Class name in Javascript = AxSelection

**Exposed attributes**

*queryCount*

The number of queries inside the Selection Document

*axoidCount* (not implemented yet)

The number of AXOIDs inside the Selection Document

**Exposed methods**

*AxSelection()*

Empty constructor

*AxSelection(string xml)*

Constructor for creating a selection document by using the XML string

*resolve(string user, string pwd)*

**AXMEDIS Project**
It resolves all the selection document by using the user and password for accessing to the MainQuerySupport

`resolveQuery(string user, string pwd, number queryId)`

It resolve a specific query of the Selection Document by using the queryId and the user and password for accessing to the MainQuerySupport

`array getAxoidList()`

It returns an array with predefined AXOIDs

`array getAXDBResult()`

It returns an array with the list of AXOIDs retrieved by the AXMEDIS Database

`array getCrawlerResult()`

It returns an array with the list of AXOIDs retrieved by the Crawler (not implemented yet)

`array getAxepToolResult()`

It returns an array with the list of AXOIDs retrieved by the AXEPTool (not implemented yet)

`load(number selId)`

Load a Selection Document specified by the selId. The document is loaded from the UserSelectionArchive (not implemented yet)

### 11.7.3 Examples of usage

The following example shows the usage of a selection object. The selection instance is a global object that manages a selection parameter provided by the AXCP Rule. In the example, the selection is used to actualised the first query ('0'). The `resolveQuery` method allows to call the MainQuerySupport and `getAXDBResult` method provides the list of AXOIDs returned as result (Actualisation).

```javascript
function test() {
    var imgFormat = getMimeType(format);

    //actualisation of selection
    selection.resolveQuery("test", "test", 0);

    //getting the AXOIDs
    var documentList = selection.getAXDBResult();
    for (i in documentList) {
        uri = "axdb://"+documentList[i];
        var axmedisObject = new AxmedisObject(uri);
        var dublinCore = axmedisObject.getDublinCore();
        var title = dublinCore.getDCElementValue("title")+"_Resized";
        var newObj = new AxmedisObject();
        cloneAxmedisObject(axmedisObject, newObj);
        createDC(newObj, title);
        adaptAxImages(newObj, h, w, imgFormat);
        print("Storing Object on disk");
        newObj.save(resourcePath+title+".axm");
    }
    return true;
}
```

//Entry point of the script
test();
11.7.4 Technical and Installation information

The JS Class comes in the form of a static LIB.

| References to other major components needed |                      |
| Problems not solved                        |                      |
| Configuration and execution context        | It is used within the AXCP Rule Editor and Engine. |

Information about the installation of JS modules within the AXCP Rule Editor and Engine can be found in section “AXMEDIS DATA Types and Functions for JavaScript”.

11.8.1 General Description of the Module

It is the AXMEDIS searchbox javascript bridge, developed by focuseek for use with the SpiderMonkey JavaScript Engine.

11.8.2 Module Design in terms of Classes

The searchbox bridge provides the following set of JS classes:

- **AXSearchbox**: The main object for accessing searchbox.
- **Document**: Used to handle documents as opaque objects.
- **MetadataValue**: Used to hold metadata.
- **QueryParser**: Used to specify the query string parser to use.
- **QueryInfo**: Used to specify the information returned as result of a query.
- **QueryView**: Used to restrict the set of documents returned as result of a query.
• **QueryAtomType**: Used to specify the type of a QueryAtom.
• **QueryAtom**: Used to build a query in RPN notation.
• **QuerySliceWeight**: Used to specify slice weights.
• **QuerySpec**: Used to submit a query.
• **QueryResult**: Used to return information on a query result

These classes are available in the AXSBJS DLL that is registered via the AXSBJSInit() function.

### 11.8.3 Draft User Manual

The AXSBJS DLL provides a single entry point, called AXSBJSInit(), it must be used during the SpiderMonkey initialization phase. This function registers the following classes that are required to communicate with the searchbox engine.

**AXSearchbox**
The main object for accessing searchbox.
Class name in the Javascript is `AXSearchbox`

**Exposed Properties:**
• `host` [string] - Host where searchbox server is running.
• `port` [string] - Port where searchbox server is listening.
• `username` [string] - Username for authentication.
• `password` [string] - Password for authentication.

**Exposed Methods:**
• `integer query(in QuerySpec query, out QueryResults[] results)`: Performs the query specified by query and returns matching documents into results. The maximum number of results is returned.
• `string addDocument(in integer arcid, in string url, in Document doc)`: Adds a document to the specified arcid. The URL of the document is specified in url and the document in doc. The ID of the document is returned. The caller must have write access rights for the archive where the document is stored.
• `void removeDocument(in string docid)`: Removes a document from the archive it belongs. The ID of the document is specified in docid. The caller must have write access rights for the archive where the document is stored.
• `Document getDocument(in string docid)`: Returns the cached copy of the page with specified docid. The document is returned. The caller must have read access rights for the archive where the document is stored.
• `string getDocumentFFF(in string docid)`: Returns the FFF representation of the page with specified docid. The FFF XML is returned. The caller must have read access rights for the archive where the document is stored.
• `DocumentMetadata getDocumentMetadata(in string docid)`: Returns an object that describes the metadata associated to the document (either applied via MetadataTemplates, or stored in the FFF). The caller must have read access rights for the archive where the document is stored.
• `string getDocumentURL(in string docid)`: Returns the URL of the document docid. The caller must have read access rights for the archive where the document is stored.
• `string normalizeURL(in string url)`: Returns the normalized URL.
• `void applyMetadataTemplate(in string docid, in integer templateid, in MetadataValue[] metadata)`: Applies a MetadataTemplate to a document, with the specified variable metadata. The caller must have write access rights for the archive where the document is stored.
• `void deapplyMetadataTemplate(in string docid, in integer templateid)`: Deapplies a metadata template from a document. The caller must have write access rights for the archive where the document is stored.
• integer[] enumAppliedMetadataTemplates(in string docid) - Returns the IDs of the applied MetadataTemplates for the specified document. The caller must have read access rights for the archive where the document is stored.

**Document**
Used to handle documents as opaque objects.
Class name in the Javascript is *Document*

**Exposed Properties:**
- mimeType [string] - MIME type of the document.
- Methods:
  - void read(in string filename) - Reads document from file.
  - void write(in string filename) - Writes document to file.
  - void readFromBuffer(in integer address, in integer size) - Reads a document from a memory buffer at the specified address with the specified size.
  - void writeToBuffer(in integer address, in integer size) - Writes a document in a memory buffer at the specified address with the specified maximum size.

**MetadataValue**
Used to hold metadata.
Class name in the Javascript is *MetadataValue*

**Exposed Properties:**
- key [string] - Metadata key.
- slice [integer] - Slice where metadata is stored.
- value [string] - Metadata value.

**DocumentMetadata**
Used to describe the metadata associated with a document.
Class name in the Javascript is *DocumentMetadata*

**Methods:**
- string getValue(in string key) - Gets the first value of the metadata with the specified key. Returns and empty string if the metadata was not found.
- string[] getValues(in string key) - Gets all the values of the metadata with the specified key.
- MetadataValue getMetadataValue(in string key) - Gets the first MetadataValue object for the metadata with the specified key. Returns null if the metadata was not found.
- MetadataValue[] getMetadataValues(in string key) - Gets all the MetadataValue objects for the metadata with the specified key.
- MetadataValue[] getAllMetadataValues(in string key) - Gets all the MetadataValue objects for every metadata of the document.

**QueryParser**
Used to specify the query string parser to use.
Class name in the Javascript is *QueryParser*

**Static Exposed Properties:**
- NOPARSER - Don't parse, the query is submitted using QueryAtoms.
- RPNPARSER - Use the RPN parser.
• ALGPARSER - Use the ALG parser.
• NETPARSER - Use the NET parser.

**QueryInfo**
Used to specify the information returned as result of a query.
Class name in the Javascript is *QueryInfo*

**Static Exposed Properties:**
• INFO_NONE - For each result no additional info is returned.
• INFO_URL - For each result the URL is returned.
• INFO_TITLE - For each result the URL and the title is returned.
• INFO_CONTEXT - For each result the URL, the title, the mime type and the contexts where the keywords specified into the query have been found are returned.
• INFO_TEMPLATE_METADATA - For each result the URL, the title, the mime type, the contexts where the keywords specified into the query have been found and the metadata added by templates to the document are returned.
• INFO_ALL_METADATA - For each result the URL, the title, the mime type, the contexts where the keywords specified into the query have been found and all the metadata of the document are returned.

**QueryView**
Used to restrict the set of documents returned as result of a query.
Class name in the Javascript is *QueryView*

**Static Exposed Properties:**
• VIEW_PUBLISHED - The query is applied to all the documents currently in the archive.
• VIEW_CORECHANGED - The query is applied only to the documents currently in the archive that have changed in the core of the text. Only applicable to an historicizing archive.

**QuerySort**
Used to specify the sorting of documents returned as result of a query.
Class name in the Javascript is *QuerySort*

**Static Exposed Properties:**
• SORT_STANDARD - The standard sorting is used.
• SORT_RELEVANCE - The documents are ordered by relevance score.
• SORT_SCORE - The documents are ordered by their intrinsic score.
• SORT_TIME_NEWER - The documents are ordered by change timestamp, more recently changed documents first.
• SORT_TIME_OLDER - The documents are reverse-ordered by change timestamp, least recently changed documents first.

**QueryAtomType**
Used to specify the type of a QueryAtom.
Class name in the Javascript is *QueryAtomType*

**Static Exposed Properties:**
• ATOM_WORD - QueryAtom is a keyword to find.
• ATOM_WILDCARD_WORD - QueryAtom is a keyword with wildcards to find.
• ATOM_NOT - QueryAtom is a logic NOT.
• ATOM_AND - QueryAtom is a logic AND between other QueryAtoms.
• ATOM_OR - QueryAtom is a logic OR between other QueryAtoms.
• ATOM_NEAR - QueryAtom is logic NEAR between words.
• ATOM_META - QueryAtom is a meta-keyword to find.
• ATOM_META_RANGE - QueryAtom is a meta-keyword range to find.
• ATOM_WILDCARD_META - QueryAtom is a meta-keyword with wildcards to find.

**QueryAtom**

Used to build a query in RPN notation.

Class name in the Javascript is `QueryAtom`  

**Exposed Properties:**

- type [integer] - Current QueryAtom type (from QueryAtomType).
- meta [string] - Contains the meta-keyword type. Only for META QueryAtoms.
- param [string] - If the current type is WORD or META it contains the keyword (or meta-keyword) to find. Otherwise, if the current type is AND, OR or NEAR it contains the decimal representation of the number of QueryAtom involved in the expression, and if the current type is META_RANGE it contains the lower boundary of the range. For the NOT type, only the value "1" is allowed in this field.
- param1 [string] - If the current type is META_RANGE it contains the upper boundary of the range. Otherwise, if the current type is NEAR it contains the decimal representation of the sloppyness allowed. An empty or 0 sloppyness makes the NEAR match an exact phrase, a sloppyness greater than 0 sets the maximum number of keyword swaps that can be made to match the query.

**QuerySliceWeight**

Used to specify slice weights.

Class name in the Javascript is `QuerySliceWeight`  

**Exposed Properties:**

- slice [integer] - Dict ID. The following dict IDs can be used:
  - 0. Author
  - 1. Keyword
  - 2. Abstract
  - 3. Invisible
  - 4. Marginal normal text
  - 5. Marginal emphasized text
  - 6. Marginal link text
  - 7. Marginal remote link text
  - 8. Marginal header text
  - 9. Central normal text
  - 10. Central emphasized text
  - 11. Central link text
  - 12. Central remote link text
  - 13. Central header text
  - 14. Title
- weight [integer] - Slice weight. Must be greater or equal to 0.

**QuerySpec**

Used to submit a query.

Class name in the Javascript is `QuerySpec`  

**Exposed Properties:**

- archives [array of integers] - IDs of the archives you want to query. Leave empty if you want to query a collection or a watch.
• collection [integer] - ID of the collection you want to query. If you want to query archives or a watch, use 0.
• watch [integer] - ID of the watch you want to query. If you want to query archives or a collection, use 0.
• firstDoc [integer] - Index of the first document (starting from 0) returned. It must be less than lastDoc.
• lastDoc [integer] - Index of the last document (starting from 0). It must be greater than firstDoc.
• minTime [integer] - Oldest Timestamp (expressed in number of seconds since January 1st 1970 GMT) of query results. All older documents will be rejected.
• maxTime [integer] - Newest Timestamp (expressed in number of seconds since January 1st 1970 GMT) of query results. All newer documents will be rejected.
• minScore [integer] - Minimum score of query results. All documents with lower score will be rejected.
• info [integer from QueryInfo] - Detail level of query results.
• view [integer from QueryView] - Document set restrictions of query.
• sort [integer from QuerySort] - Result document set sorting type.
• parser [integer from QueryParser] - Parser to use to parse the query string.
• query [array of QueryAtoms] - Query in RPN notation all list of QueryAtoms. The QueryAtom sequence must produce a stack with only one element. Only used if NOPARSER is specified as QueryParser.
• queryString [string] - Query string to be parsed. Only used if RPNPARSER, ALGPARSER or NETPARSER is specified as QueryParser.
• weights [array of QuerySliceWeights] - Slice weights. You can pass an empty vector to use the default slice weights. To disable a slice in the current query, you must pass an entry for the slice with a weight of 0. If you don't pass an entry for a certain slice, that slice will have its default weight.

QueryResult
Used to return information on a query result.
Class name in the Javascript is QueryResult

Exposed Properties:

• id [string] - ID of the document, guaranteed to be unique across archives.
• url [string] - URL of the document.
• title [string] - Title of the document.
• mimeType [string] - Mime type of the document.
• contexts [array of strings] - Contexts of the document where the keywords have been found.
• timestamp [integer] - Document timestamp (expressed in number of seconds since January 1st 1970 GMT).
• serverTime [integer] - Document timestamp (expressed in number of seconds since January 1st 1970 GMT), as reported by the server.
• score [integer] - Document score (expressed as percentage * 10000).
• archives [array of integers] - The archives the document belongs to.
• categories [string] - Private use.
• metadata [array of MetadataValues] - Metadata associated with the document.
• templates [array of integers] - IDs of the MetadataTemplates applied to the document.

11.8.4 User interface description
No specific user interface.
11.8.5 Technical and Installation information

The bridge comes in the form of a redistributable DLL, a stub library (MSVC71 format) for linking to the DLL, include files and dependancy DLL libraries. To install the bridge, copy the dlls somewhere in your path (preferably on the same directory where the main program that links to the library resides), and place stub library and include files in the correct place for your development system.

11.9 JS_Protection (FHGIGD)

The JS_Protection class provides the protection methods, which are needed by the rules editor, to the JavaScript.

The following functionalities are provided by JS_Protection as a JavaScript stub using AXOM and PMS:

- Requesting keys from PMS (encryption keys)
- Applying Protection to AXMEDIS object : encryption, scrambling, compression, FP.
- Creation of new Protection Information
- Sending the Protection Information (keys and parameter, see IPMP standard of MPEG21) to the database of the AXCS via the PMS

**JS_ProtectionInfo**

The protection information holds the IPMP information as stated in MPEG-21 Part 4 IPMP standard and more. The information may include:

- How each element of an AXMEDIS object has been protected, i.e. encrypted, encoded, compressed and scrambled.
- How each chunk of a resource has been protected, e.g. specifying that a given set of protection tools has to be applied from byte X to byte Y of a given resource (and not to the whole resource). In that way, different protection can be applied to a resource along its consumption.
- It is based on an XML schema which allows to describe sort of protection procedures as en-/decryption, (de-)compression, (de-)scrambling

The syntax and semantics is still under discussion, the actual state of the standard is contained in the output document w6772 of the 70th MPEG meeting (see http://mpeg.nist.gov/).

MPEG-21 Part 4 divides protection information into two XML schemas:

- one is used to declare the list of needed protection tools (or commands as defined in this section) to unprotect the whole digital item;
- the other is used to describe, for each protected element, how to use those tools (e.g. the execution order, keys, initialization parameters, etc…) to unprotect a specific element.

**JS_ProtectionStamp**

To identify the correct ProtectionInfo for an AXMEDIS object also the so-called ProtectionStamp is needed which binds an object to the different protection models that can be applied to the object.

11.9.1 Module Design in terms of Classes

The development of these modules is on-going work. For the structure of the protection functions and Protection Information please take a look at the specification of the Protection Processor.

11.9.2 Technical and Installation information
<table>
<thead>
<tr>
<th>References to other major components needed</th>
<th>Protection Processor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Problems not solved</td>
<td>On-going work.</td>
</tr>
<tr>
<td>Configuration and execution context</td>
<td>JS_Protection is used within the AXCP Rule Editor and Engine.</td>
</tr>
</tbody>
</table>

Information about the installation of JS modules within the AXCP Rule Editor and Engine can be found in section “AXMEDIS DATA Types and Functions for JavaScript”.

### 11.9.3 Draft User Manual
This module is on-going work. A detailed user manual will be available when the work is completed.

### 11.9.4 Examples of usage
This module is on-going work, examples will be available when the work has made more progress.

### 11.9.5 Integration and compilation issues
Please refer to section “AXMEDIS DATA Types and Functions for JavaScript”, for information about integrating an compilation issues of JS modules within the AXCP Rule Editor and Engine.

### 11.10 JS_DRM (FHGIGD)
JS_DRM defines the DRM data type and methods for the Protection Tool Engine.

The following functionalities are provided by JS_DRM as a JavaScript stub using AXOM and PMS:

- Creating a new governed object (with license)
- Sending a License to the PMS and saving the license into the database
- Loading a License from the database via the License ID
- Loading a License Model from the database via the License Model ID
- Generating a license from license model and additional information (principal, AXOID)
- Check/Verification of an issued License against some RIGHTS written in clear such as: “the play on the AXOID 34 in July 2005 for 5 times, the print of AXOID 56 in Spain in May 2006 at least one, etc.”
- Check/Verification if it is possible to issue/generate a License with some RIGHTS written in clear such as: “the play on the AXOID 34 in July 2005 for 5 times, the print of AXOID 56 in Spain in May 2006 at least one, etc.”
- Check/Verification of existing PAR against some RIGHTS written in clear such as: “the play on the AXOID 34 in July 2005 for 5 times, the print of AXOID 56 in Spain in May 2006 at least one, etc.”
- Addition of rights or removal from a license (license adaptation): Generation of a new license (with new or less rights) AND Revocation of the old licenses in ONE TRANSACION
- Addition of rights or removal from a PAR (PAR adaptation): Generation of a new PAR (with new or less rights) AND Revocation of the old licenses in ONE TRANSACION
- Check/Verification of license against PAR

In order to express DRM rules associated to AXMEDIS objects it has been decided to use MPEG-21 REL as primary rights expression language. A common structure is imposed for licenses and PAR.

### JS_License – class that models a License
The following objects are needed to fully represent a license and all of its components in JavaScript:

- JS_License
- JS_Issuer
- JS_GrantGroup
- JS_Grant
Each license has an issuer and a GrantGroup. Each GrantGroup contains a set of Grants. Each Grant contains the information of the right granted, the resource, the principal and an optional set of conditions related to that right. In addition, we have to realise that a resource can be a GrantGroup (in case of Distributor Licenses).

For expressing the different types of conditions JS_CONDITION, the following information was defined:
- ConditionType: It indicates which kind of condition we are expressing.
- Five Tvalue fields and two NValue fields (more can be added if desired), whose values depend on the conditionType.

**JS_PAR – class that models a PAR**

The following objects are needed to fully represent a PAR and all of its components in JavaScript:
- JS_PAR
- JS_Grant
- JS_Right
- JS_Resource
- JS_Condition
  - Fee
  - Territory
  - Number
  - Interval

The relationship between the different objects and the meaning is the same as for JS_LICENSE.

**11.10.1 Module Design in terms of Classes**

11.10.3 Draft User Manual
This module is on-going work. A detailed user manual will be available when the work is completed.

11.10.4 Examples of usage
In the following a Javascript source code is reported as example of usage:

```javascript
var x = new PMSClient();

var issuerName = "Pepe";

var licenseTmpId = "ResourceID";
var principal = "Hans";
var diResource = false;
var diltem = true;
var AXOID = "1F 2E 3A";
var right = "play";
```

AXMEDIS Project
var validityInterval = false;
var notBefore = "";
var notAfter = "";
var countLimit = true;
var limit = 1000;
var validityRegion = true;
var country = "Spain";
var region = "";
var feeType = 0;
var fee = 0.8;
var currency = "";
var bankAccount = "";
var adaptationRules = "";

//license initialisation
x.initLicenseEndUser(issuerName);
//x.initFinalUser(issuerName);

/ * Input:                     arg     
    * string licenseTmpId   0
    * string principal      1
    * bool diResource       2
    * bool diItem           3
    * string AXOID          4
    * string right          5
    * bool validityInterval  6
    * string notBefore      7
    * string notAfter       8
    * bool countLimit       9
    * int limit             10
    * bool validityRegion   11
    * string country        12
    * string region1        13
    * int feeType           14
    * float fee             15
    * string currency       16
    * string bankAccount    17
    * string adaptationRules 18
    */

//adding grant
x.addGrantEndUser(
    licenseTmpId,
    principal,
    diResource,
    diItem,
    AXOID,
    right,
    validityInterval,
    notBefore,
    notAfter,
    countLimit,
    limit,
    validityRegion,
country,
region,
feeType,
fee,
currency,
bankAccount,
adaptationRules);

//adding grant
/*x.addGrantFinalUser("TempId2","Joe",true,true,"AXOID",right,
validityInterval,notBefore,notAfter,countLimit,limit,validityRegion,
"Italy",region,feeType,45.76,currency,bankAccount,adaptationRules);
*/

//adding grant
x.addGrantFinalUser("Bill",diResource,diItem,diText,diType,right,
validityInterval,notBefore,notAfter,countLimit,limit,validityRegion,
"Germany",region,feeType,0.0,currency,bankAccount,adaptationRules);
*/

//finalizing user
x.finaliseLicenseEndUser(licenseTmpId);

rval = "license successfully created"

11.10.5 Integration and compilation issues
Since JS_Protection is part of the AXMEDIS Content Processing (AXCP) it has to be compile as an integrated part. The following variables have to be set to the correct path to compile JS_Protection as part of the AXMEDIS Rule Editor: XERCES, XERCESROOT, OPENSSL, OPEN_SSL, MYSQLROOT, MYSQL++, MOZILLA, LIBCURL and JS, WXWIN.

</tbody>
</table>
The following structure have been identified to delegate the movements of objects to instances of the AXCP Engine, thus simplifying the work related to the creation of the P2P. This approach allows to decouple the database of the AXMEDIS factory with respect to the databases of input and output of the P2P B2B network. Continuous line represent the flow of the Data amongs Databases and P2P environment, dashed line explains the functional link amongs Databases and P2P environment.

All the databases are instance of the AXDB. The AXCP Scheduler and Engine are instances of the AXCP tools. All the JS modules are used for creating scripts and automating the movements of objects from and to the P2P B2B Network represented on the right as P2P. The In and Out DB are the possible internal Databases or filesytem provided by the P2P tool. WS stands for WebServices provided by the interface that allows using the internal functionalities of the P2P tool.

JS Publisher, JSLoader and JSDownloader are the Javascript classes that will exposer methods to realize the movement of the object, in particular the JSPublisher and JSDownloader could host an instance of the WebServiceConnection class to realize the internal client for directly accessing to WebServices. Alternatively, the WebServiceConnection class could be used in the script by using the JSWebConnetion object and realize the WebService access indirectly via script.

### 11.11.1 Module Design in terms of Classes
JSDownloader (DSI)
The JSDownloader class wraps the class that controls the download of AXMEDIS objects form the P2P environment. The main methods exposed by the JSDownloader are:

- abort(), it aborts the download of the object specified by the id.
- download(), it starts the download of the object specified by the id in the P2P environment;
- monitor(), it provides the current status of the downloading objects in the P2P environment. It returns a list if ids with the current percentage of download
- copyObject(), it retrieves the object from the internal P2P database and put it into the AXDB In
- removeObject(), it deletes the object specified by the id from the internal P2P database

JSLoader (DSI)
The JSLoader Javascript class wraps the class for loading/transfering AXMEDIS objects from the AXDB In Database to the Factory AXMEDIS Database. The main methods exposed by the JSLoader are:

- copyObject(), it transfers an AXMEDIS Object from the AXDB In to the Factory AXMEDIS Database
- getObjectsList(), it returns the ID of objects in the AXDB In
- removeObject(), it removes the object from the AXDB In

JSPublisher (DSI)
The JSPublisher Javascript class wraps the class for loading/transfering AXMEDIS objects from the Factory AXMEDIS Database to the AXDB Out Database and/or to the P2P internal DB. The main methods exposed by the JSPublisher are:

- copyObject(), it transfers an AXMEDIS Object from the Factory AXMEDIS Database to the AXDB Out
- getObjectsList(), it returns the ID of objects in the AXDB Out
- removeObject(), it removes the object from the AXDB Out
- putObject(), it puts an AXMEDIS object into the P2P internal DB by means of a specific call to the WebService of the P2P. The transfer does not involve the AXDB Out and could be used to bypass this AXDB avoiding to duplicate object and using another Database instance.

11.11.2 Technical and Installation information
Information about the installation of JS modules within the AXCP Rule Editor and Engine can be found in section “AXMEDIS DATA Types and Functions for JavaScript”.

JS Functions is a set of auxiliary functions wrapped into Javascript. They will be divided into the following categories:

Statistical
- MAX – return the maximum value of an numerical array
- MIN - return the minimum value of an numerical array
- VAR – return the variance of an numerical array
- AVERAGE – return the average of an numerical array
- MODE – return the mode of an numerical array

Combinatorial
- Data Permutation
- Sort data

Set Management
• Intersection – \( A \cap B \), it will return the list of common items
• Union – \( A \cup B \), it will return the list of items as union of sets
• Inclusion – return true if \( A \subseteq B \neq \emptyset \)

**Generic**

• File system functions – File exists, dir exists, create dir, etc…
• Communication functions – A function will provide the support for the communication via JavaScript. Messages will be routed via the Engine to the Axmedis Workflow Manager.

### 11.12.1 Module Design in terms of Classes

#### File system functions

- `FileExists(string filePath)`: Test if a file at `filePath` exists. Returns `true` if the file exists, `false` otherwise.
- `DirectoryExists(string dirPath)`: Test if a directory at `dirPath` exists. Returns `true` if the directory exists, `false` otherwise.
- `CreateDirectory(string dirPath)`: Create a directory at `dirPath`.
- `RemoveFile(string filePath)`: Remove a file at `filePath`.
- `CopyFile(string sourcePath, string targetPath)`: Copy the file at `sourcePath` to `targetPath`.
- `GetFilesList(string path)`: Provide the list of files in the `path` folder.

#### Change file extension

- `ChangeFileExtension(string filePath, string newExtension)`: Change the file extension of a file at `filePath` to `newExtension`.

### 11.12.2 Draft User Manual

#### I/O functions

- `Print(string msg)`: Print a string on the current I/O device. It could be the GUI, the console or other.

#### File functions

- `WriteToFile(string filePath, string buffer)`: Write a string buffer to a file at `filePath`.
- `AppendToFile(string filePath, string buffer)`: Write a string buffer to a file at `filePath`.
- `RemoveFile(string filePath)`: Remove a file at `filePath`.
- `ExistsFile(string filePath)`: Test if a file at `filePath` exists. Returns `true` if the file exists, `false` otherwise.
- `ReadFromFile(string filePath)`: Return a string buffer from a file at `filePath`.
- `CopyFile(string sourcePath, string targetPath)`: Copy the file at `sourcePath` to `targetPath`.
- `GetFilesList(string path)`: Provide the list of files in the `path` folder.
- `ChangeFileExtension(string filePath, string newExtension)`: Change the file extension of a file at `filePath` to `newExtension`.
Dir functions
createDir(string dirPath)
Create a directory at dirPath

removeDir(string dirPath)
Remove the directory at dirPath

boolean existsDir(string dirPath)
Test if the directory at dirPath exists

changeDir(string dirPath)
Command to change the folder path into the filesystem

Process Functions
execute(string lineCommand)
Invoke the execution of an external process/application by means the line command and parameters
The call is synchronous.

Mime Type Functions
string getMimeType(string ext)
Get the mime type from the file extension

string mimeTypeToExt(string mimetype)
Get the extension from the mime type

11.12.3 Examples of usage
The script parse an xml string loaded from filesystem the xml is loaded by means the 'readFromFile' function that returns a string with the xml. The ShowXML calls the function in the showXML script. It uses the XML parser provided by the "rexml" script. Such script define an XML object in JS and gives some tools to browse and retrieve information from the xml elements

```
var str = readFromFile(xml);
var obj = new AxMetadata();
obj.addXML(str);
var xml = obj.getXML();
ShowXML(xml);

function ShowXML(strXML) {
    var xmlDoc = new REXML(strXML);
    print("The root element " + xmlDoc.rootElement.name + " has " +
    xmlDoc.rootElement.childElements.length + " child elements.");
    for (var i=0; i<xmlDoc.rootElement.childElements.length; i++) {
        var item = xmlDoc.rootElement.childElements[i];
        print("Child element of type " + item.type + " " +item.name );
    }
}
```

11.12.4 Technical and Installation information
The JSFunctions comes in the form of a static LIB. The initJSFunction has to be called in the source code where the Engine is initialized. This is necessary to add the set of functions to the Javascript Engine.

The user’s profile captures and stores information related to the users, the usage environment and the user preferences. This profile should be managed at the personalization server and be able to store minimal details about the user to identify his personal preferences in respect to the services being offered. The elements in this profile are the minimal set of elements that is required to meet the AXMEDIS User’s personalization needs. Each of these elements are based on the definitions provided by MPEG21 schema [ISO MPEG-21, Part 7 - Digital Item Adaptation, ISO/IEC JTC1/SC29/WG11/N5231, (Oct 2002)]. The schema for this profile is contained in axmedis-user-profile.xsd The JSUserProfile is a JS class to automatically create and manage user profiles as a part of rule scripts for AXCP engine.

The functionalities and values for the user profiles can be accessed through the methods given below. These functions are only wrappers for the functions in the c++ class UserProfile.

- **UserProfile**: Constructor for Initialising the Profile
- **loadXmlFile**: Loading the Xml from file
- **loadXmlString**: Loading Xml from an Xml String
- **createXmlFile**: Create and Xml file where the file is specified as uri
- **getXml**: Returns the contents of the XML file in String form
- **setXml**: Write the string as the contents of the XML file
- **getAttribute**: It returns the corresponding value of the attributes from the xml file. Attributes for the respective profiles are specified in the Profiles documentation provided in the Appendix
• **setAttribute**: Sets an individual values to the attributes of the xml file

• **getValue**: It returns the corresponding value of the element from the xml file. Possible Values for the respective profiles are specified in the Profiles documentation provided in the Appendix

• **setValue**: Sets an individual values to the elements of the xml file

• **createElement**: Create an xml element using the DomPath and Element Name

• **deleteElement**: Delete an xml element based on the DomPath

• **close**: Closes the xml file. If any element is change then the changes are saved and then the xml file is closed.

**11.13.1 Module Design in terms of Classes**

The user profile is a valid XML file based on following Schema. For entire schema file please refer to the axmedis-user-profile.xsd.

```xml
<?xml version="1.0"?><!

</table>

11.13.3 Draft User Manual

Exposed Methods

`UserProfile()`  
Constructor for Initialising the Profile

`loadXmlFile(String uri)`  
Loading the Xml from file

`loadXmlString(String XmlString)`  
Loading Xml from an Xml String

`createXmlfile(String uri)`  
Create and Xml file where the file is specified as uri

`String getXml ()`  
Returns the contents of the XML file in String form

`setXml (String XmlString)`  
Write the string as the contents of the XML file

`String getAttribute( String DomPath, String Attribute)`  
It returns the corresponding value of the attributes from the xml file. Attributes for the respective profiles are specified in the Profiles documentation provided in the Appendix

`setAttribute(String DomPath, String Attribute, String value)`
Sets an individual values to the attributes of the xml file

**getValue(String DomPath)**
It returns the corresponding value of the element from the xml file. Possible Values for the respective profiles are specified in the Profiles documentation provided in the Appendix

**setValue(String DomPath, String value)**
Sets an individual values to the elements of the xml file

**createElement(String DomPath, String ElementName)**
Create an xml element using the DomPath and Element Name

**deleteElement(String DomPath)**
Delete an xml element based on the DomPath

**close()**
Closes the xml file. If any element is change then the changes are saved and then the xml file is closed.

### 11.13.4 Examples of usage

Sample Java Script code to get the value of a user-profile element and set it with user specified value.

```javascript
var userprofile= new UserProfile(); // Initialises the User Profile
userprofile.loadXmlFile("C:\axmedis\testProfile.xml"); // Loads an xml file into the profile class

// Get the volume preference of the user
var volume= userprofile.getValue("Preferences/AudioPreferences /VolumeControl");

//set the volume preference of the user
userprofile.setValue("Preferences/AudioPreferences /VolumeControl","0.5");

//Close the file
userprofile.close();
```

### 11.13.5 Integration and compilation issues

None

### 11.14 JSDeviceProfile (IRC)

*AXMEDIS Project*
Device profile captures information related to user’s device, that the service provider must take into account while delivering the contents. Generally the minimal set of elements required are those that affect the proper utilization of the contents on the device e.g. screen resolution for images. This profile represents the characteristic of the user’s personal device and hence contains most vital information for the content providers that can be used to transcode the content to match the device characteristic and can be better utilized by the user. Each of these elements are based on the definitions provided by MPEG21 schema [ISO MPEG-21, Part 7 - Digital Item Adaptation, ISO/IEC JTC1/SC29/WG11/N5231, (Oct 2002)]. The schema for this profile is contained in axmedis-device-profile.xsd The JSDeviceProfile is a JS class to automatically create and manage Device profiles as a part of rule scripts for AXCP engine.

The functionalities and values for the device profiles can be accessed through the methods given below. These functions are only wrappers for the functions in the c++ class DeviceProfile.

- **DeviceProfile**: Constructor for Initialising the Profile
- **loadXmlFile**: Loading the Xml from file
- **loadXmlString**: Loading Xml from an Xml String
- **createXmlfile**: Create and Xml file where the file is specified as uri
- **getXml**: Returns the contents of the XML file in String form
- **setXml**: Write the string as the contents of the XML file
- **getAttribute**: It returns the corresponding value of the attributes from the xml file. Attributes for the respective profiles are specified in the Profiles documentation provided in the Appendix
- **setAttribute**: Sets an individual values to the attributes of the xml file
- **getValue**: It returns the corresponding value of the element from the xml file. Possible Values for the respective profiles are specified in the Profiles documentation provided in the Appendix
- **setValue**: Sets an individual values to the elements of the xml file
- **createElement**: Create an xml element using the DomPath and Element Name
- **deleteElement**: Delete an xml element based on the DomPath
- **close**: Closes the xml file. If any element is change then the changes are saved and then the xml file is closed.

11.14.2 Technical and Installation information
The JS class comes in the form of a static LIB. The init method has to be called in the source code where the Engine is initialized. This is necessary to add the set of functions to the Javascript Engine.

| References to other major components needed |   |
| Problems not solved | ● |
| Configuration and execution context |   |

(DeviceProfile()
   Constructor for Initialising the Profile

loadXmlFile(String uri)
   Loading the Xml from file

loadXmlString(String XmlString)
   Loading Xml from an Xml String

createXmlFile(String uri)
   Create and Xml file where the file is specified as uri

getXml() 
   Returns the contents of the XML file in String form

setXml (String XmlString)
   Write the string as the contents of the XML file

getAttribute(String DomPath, String Attribute)
   It returns the corresponding value of the attributes from the xml file. Attributes for the respective profiles are specified in the Profiles documentation provided in the Appendix

setAttribute(String DomPath, String Attribute, String value)
   Sets an individual values to the attributes of the xml file

getValue(String DomPath)
   It returns the corresponding value of the element from the xml file. Possible Values for the respective profiles are specified in the Profiles documentation provided in the Appendix

setValue (String DomPath, String value)
   Sets an individual values to the elements of the xml file

createElement(String DomPath, String ElementName)
   Create an xml element using the DomPath and Element Name

deleteElement(String DomPath)
Delete an xml element based on the DomPath

close()
Closes the xml file. If any element is change then the changes are saved and then the xml file is closed.

**11.14.4 Examples of usage**
Sample code to demonstrate copying one device profile into another file is given below. This example is mainly to demonstrate the methods used for retrieving the xml contents from a file and writing it to another file.

```javascript
var deviceprofile1 = new DeviceProfile();  // Initialises the Device Profile for the source xml file
var deviceprofile2 = new DeviceProfile();  // Initialises the Device Profile for the destination xml file

// Loads an source xml file
deviceprofile1.loadXmlFile(“C:\axmedis\sourceProfile.xml”);
// Retrieves the xml-string from the xml file and stores it into the variable xml
var xml = deviceprofile1.getXml();

// Creates the destination xml file
deviceprofile2.createXmlfile(“C:\axmedis\destProfile.xml”);
// Sets the contents for the destination xml file
deviceprofile2.setXml(xml);

// Closing both the xml files
deviceprofile1.close();
deviceprofile2.close();
```

**11.14.5 Integration and compilation issues**
none

Network profile captures information related to the carrier that is used for delivery of the content to the user’s device. It is necessary for the distributors to know various characteristics of the Network so as to provide the promised QoS. The information contained in this profile can also be used to for transcoding of the contents to better utilize both network and device capabilities. The elements in this profile are the minimal set of elements that is required to meet the AXMEDIS User’s personalization needs and to meet the distributor’s needs in terms of the network capabilities. Each of these elements are based on the definitions provided by MPEG21 schema [ISO MPEG-21, Part 7 - Digital Item Adaptation, ISO/IEC JTC1/SC29/WG11/N5231, (Oct 2002)]. The schema for this profile is contained in axmedis-network-profile.xsd. The JSNetworkProfile is a JS class to automatically create and manage user profiles as a part of rule scripts for AXCP engine.

JS_NetworkProfile updates/retrieves the Network Profile stored in the database. It uses the following functions:

- **NetworkProfile**: Constructor for Initialising the Profile
- **loadXmlFile**: Loading the Xml from file
- **loadXmlString**: Loading Xml from an Xml String
- **createXmlfile**: Create and Xml file where the file is specified as uri
- **getXml**: Returns the contents of the XML file in String form
- **setXml**: Write the string as the contents of the XML file
- **getAttribute**: It returns the corresponding value of the attributes from the xml file. Attributes for the respective profiles are specified in the Profiles documentation provided in the Appendix
- **setAttribute**: Sets an individual values to the attributes of the xml file
- **getValue**: It returns the corresponding value of the element from the xml file. Possible Values for the respective profiles are specified in the Profiles documentation provided in the Appendix
- **setValue**: Sets an individual values to the elements of the xml file
- **createElement**: Create an xml element using the DomPath and Element Name
- **deleteElement**: Delete an xml element based on the DomPath
- **close**: Closes the xml file. If any element is change then the changes are saved and then the xml file is closed.
11.15.1 Module Design in terms of Classes
The Network profile is a valid XML file based on following Schema. Please refer to axmedis-network-profile.xsd for entire schema file.

```xml

11.15.2 Technical and Installation information

The JS class comes in the form of a static LIB. The init method has to be called in the source code where the Engine is initialized. This is necessary to add the set of functions to the Javascript Engine.

<table>
<thead>
<tr>

11.15.3 Draft User Manual

**NetworkProfile()**

Constructor for Initialising the Profile

*loadXmlFile(String uri)*

Loading the Xml from file

*loadXmlString(String XmlString)*

Loading Xml from an Xml String

*createXmlfile(String uri)*

Create and Xml file where the file is specified as uri

*getXml()*

Returns the contents of the XML file in String form

*setXml(String XmlString)*

Write the string as the contents of the XML file

*getAttribute(String DomPath, String Attribute)*

It returns the corresponding value of the attributes from the xml file. Attributes for the respective profiles are specified in the Profiles documentation provided in the Appendix

*setAttribute(String DomPath, String Attribute, String value)*

Sets an individual values to the attributes of the xml file
getValue(String DomPath)
It returns the corresponding value of the element from the xml file. Possible Values for the respective
profiles are specified in the Profiles documentation provided in the Appendix

setValue(String DomPath, String value)
Sets an individual values to the elements of the xml file

createElement(String DomPath, String ElementName)
Create an xml element using the DomPath and Element Name

deleteElement(String DomPath)
Delete an xml element based on the DomPath
close()
Closes the xml file. If any element is change then the changes are saved and then the xml file is
closed.

11.15.4 Examples of usage
Sample Java Script code to get the value of a Network -profile attribute and set it with user specified value.

var networkprofile= new Network Profile(); // Initialises the Network Profile
networkprofile.loadXmlFile(“C:\axmedis\testProfile.xml”); // Loads an xml file into the profile class

// Get the yRadius
var yrad= networkprofile.getAttribute(“Mobility/UpdateInterval”, “yRadius”);

// set the yRadius
networkprofile.setAttribute(“Mobility/UpdateInterval”, “yRadius”, 0.5”);

//Close the file
networkprofile.close();

11.15.5 Integration and compilation issues
None

The Content Format Engine functionalities and data types are accessible in JavaScript through \textit{JS\_Template}, \textit{JS\_Style} and \textit{JS\_Format} classes. They simply wrap the main classes of the C++ Format Engine:

- \textit{JS\_Template}: the interface to templates archive;
- \textit{JS\_Style}: the interface to style-sheets archive;
- \textit{JS\_Format}: the interface to selection and optimization logic, and style-sheet processing.

\subsection*{11.16.1 Module Design in terms of Classes}
\textit{JS\_Template}, \textit{JS\_Style} and \textit{JS\_Format} classes expose functionalities of the C++ Format Engine.

\begin{center}
\begin{tikzpicture}
\node[rectangle, draw] (js_format) at (0,0) {\texttt{JS\_format}};
\node[rectangle, draw] (js_template) at (-2,-2) {\texttt{JS\_template}};
\node[rectangle, draw] (js_style) at (2,-2) {\texttt{JS\_style}};
\node[rectangle, draw] (templates_management) at (-2,0) {\texttt{templates\_management}};
\node[rectangle, draw] (styles_management) at (2,0) {\texttt{styles\_management}};
\node[rectangle, draw] (format_management) at (0,2) {\texttt{format\_management}};
\draw (js_template) -- (js_format) node[anchor=east] {\texttt{\langle uses\rangle}};
\draw (js_style) -- (js_format) node[anchor=west] {\texttt{\langle uses\rangle}};
\draw (templates_management) -- (js_template) node[anchor=east] {\texttt{\langle uses\rangle}};
\draw (styles_management) -- (js_style) node[anchor=west] {\texttt{\langle uses\rangle}};
\draw (js_format) -- (format_management);
\end{tikzpicture}
\end{center}

The \textit{JS\_Format} class provides all functionalities exposed by the C++ Format\_Manager to optimize style-sheets and produce the final SMIL description of the document. \textit{JS\_Format} simply wraps the C++ format\_manager class and exposes methods for a JavaScript Rule Executor.

The \textit{JS\_Template} class provides functionalities needed to manage the template archive. \textit{JS\_Template} wraps the C++ templates\_list class and exposes methods for a JavaScript Rule Executor.

The \textit{JS\_Style} class provides functionalities needed to manage the style-sheet archive. \textit{JS\_Style} wraps the C++ styles\_list class and exposes methods for a JavaScript Rule Executor.

\subsection*{11.16.2 Draft User Manual}
In this section a draft description of the JSFormatting classes is provided in terms of Javascript language. For each class the set of exposed attributes, constructors and methods are reported.

\textbf{JS\_format}

\textbf{Exposed methods}

\texttt{addResource(String uri)}

adds a new resource to the system
addResourceDescriptor(String uri)
    adds a new XML resource descriptor to the system

clearResources()
    empties the resources list

addCriteria(String id, String type, Int[] weights, String meta)
    stores a new set of weights

setCriteria(String id)
    set criteria for next filtering operation

setDevice(String uri)

 setUser(String uri)

setContext(String uri)
    set profiles stored in the given XML file

String[] filterTemplate()
    returns a list of template IDs

String[] filterStyle(String templateId)
    returns a list of style-sheet IDs

Int[] optimize(String styleId)
    returns the optimized values for parameters

String apply(styleId, values)
    creates the SMIL document

**JS_template**

Exposed methods

templates_list(String uri)
    constructor; needs the address of the descriptors directory

load()
    fill the list with existing template descriptors

add(String id, String location, String outformat, String category, String device, String meta)
    creates a new template descriptor

String getData(String id)

String getLocation(String id)

String getMetadata(String id)

String getDevice(String id)

String getFormat(String id)

String getCategory(String id)

getter methods

String getHierarchy(String id)
    returns the XML hierarchy of the resources within the template

Int getRes(String id)
    returns the number of resources needed by the template

Int getResByType(String id)
    returns the number of resources of the given type needed by the template

Int getType(String id)
    returns the number of different resource types needed by the template

**JS_style**

Exposed methods

styles_list(String uri)
    constructor; needs the address of the descriptors directory

load()
    fill the list with existing style-sheet descriptors

add(String id, String location, String device, String metadata, String template)
    creates a new style descriptor

addStyle(String xml, String id, String device, String metadata, String template)
    creates and stores a new style-sheet and its descriptor
String getData(String id)
String getLocation(String id)
String getMetadata(String id)
String getDevice(String id)
String getTemplate(String id)
getter methods
Int getParamNum(String id)
returns the number of parameters defined within the style-sheet
String[] getParams(String id)
returns the list of parameters defined within the style-sheet

11.16.3 Examples of usage
In the following example a set of resources is extracted from an AXMEDIS object and a SMIL document is produced to integrate the resources in a multimedia presentation; finally, the SMIL document is included in the AXMEDIS object.

```javascript
var fm = new JS_Format();
// getting resources
var obj = new AxmedisObject(AXOID);
var resources = obj.getContent();
for (i=0; i < resources.length; i++) {
    // setting the resource list
    fm.addResource(resources[i]);
}
// setting profiles
fm.setDevice(myDevice.uri);
fm.setUser(myUser.uri);
fm.setContext(myContext.uri)
// filtering and optimization
var tList = fm.filterTemplate();
// Rule Executor chooses its preferred template...
var tId = tList[0];
var sList = fm.filterStyle(tId);
// Rule Executor chooses its preferred style-sheet...
var sId = fList[0];
var values = optimize(sId);
// producing SMIL
var smilResult = apply(sId, values);
// including SMIL into the AXMEDIS object
var smilResource = new AXResource(smilResult);
obj.addContent(smilResource);
```

</table>
JS_MetadataMapper is a JavaScript wrapper around the MetadataMapper C++ library. It provides the following functionalities:
1) Instantiating a MetadataMapper object within a JavaScript
2) Loading an XSLT stylesheet
3) Transforming XML from source to destination language according to the stylesheet

11.17.1 Module Design in terms of Classes
JSMDM Class

11.17.2 Draft User Manual
This is a draft User Manual for the JS classes.

JSMDM
Class name in Javascript = `MetaDataMapper`

Exposed methods

`MetaDataMapper()`
It creates a mapper object

`LoadXSLFile(string xsltFilePath)`
load an XSLT file into a DOMDocument

`LoadXSL(string xsltXMLString)`
load an XSLT string into a DOMDocument

`TransformFile(string infile, string outfile)`
transform metadata in input file according to stylesheet to create an output file

`Transform(string inxml, string outxml)`

transform metadata in an input string according to stylesheet to create an output string

### 11.17.3 Examples of usage

// Example 1: create a new file containing transformed metadata
```
var mdm = new MetaDataMapper();
mdm.LoadXSLFile(“style.xsl”);
mdm.TransformFile(“input.xml”, ”output.xml”);
```

// Example 2: create a new file containing transformed metadata
```
var input = “<?xml ..........”;
var output;
var mdm2 = new MetaDataMapper();
mdm2.LoadXSL(“style”);
mdm2.Transform(input, output);
```

### 11.17.4 Technical and Installation information

The JS Class comes in the form of a static LIB.

<table>
